will apply to taxes of wide incidence, the amounts so remitted will be applied to current consumption and the payment of the inheritance tax will undoubtedly constitute a net reduction in the volume of capital available for private investment. The final judgment in this instance hinges on the broader problem of the relative merits of public expenditure and private investment; moreover in view of the increasing participation of governments in productive enterprises the distinction loses in importance.

The argument concerning the adverse effect of high inheritance taxes on saving and accumulation is theoretical and devoid of any factual verification. A priori it can be argued with equal plausibility that the existence of high tax rates will stimulate the affectionate parent to greater accumulation in order to offset the loss which his estate will sustain from the tax.

At present the inheritance tax may be considered to have completed the experimental formative stage of its evolution. By scholars and legislators alike it is accepted as a valid source of an appreciable quota of tax revenue. Attempts at intricate graduation and discrimination to effect non-fiscal designs have been for the most part abandoned, and the trend of recent years would seem to be toward ever greater simplicity and uniformity. The major inheritance tax problem facing legislators today is that of overlapping tax jurisdictions and double taxation as between states and between nations; interstate and international reciprocity agreements together with court decisions in federal countries like the United States have gone far toward eliminating the worst features of this abuse.

INITIATION. A systematic ceremonial induction of adolescent youths into the full participation in social life is a practically universal trait of the peoples of simpler culture. Such practises represent efforts to rivet the youth securely to the regnant social order and are devices for the development of social cohesion. The initiation rites are prosecuted with special vigor when the exclusive, personal interests of the group or class are threatened by exigencies, such as initial contact with alien peoples, migration, depopulation, threat of complete extinction or absorption into outside cultures, or the *Heimweh* provoked by a novel environment. The elders under these stresses try to maintain group consciousness and custom largely through the extensive emotional and mental schooling of the manhood ceremonies, because only in this way can the social heritage be perpetuated as a living thing. Thus in Nyasaland the rite is at present being performed at an earlier age than formerly so that the youths can receive tribal instruction before they come under mission influence.

At puberty physical and emotional changes in the child become evident, and with this sexual maturity comes a critical juncture in the social position of the individual in view of the potential disturbances which may be effected in the social order. The threat to the perpetuation of things as they are produces the need for endowing the youth with knowledge of his mores and with sympathy for them and with an understanding of the responsibilities and rights accompanying sexual maturity. The initiation signifies not simply physical but full social adulthood, and the two do not necessarily converge. Considerations of a purely cultural nature may determine the age of initiation, as, for example, in the New Hebrides and Australia, where the requirement of an entrance fee results in old men being initiated along with youths.

The prestige associated with passage through

the manhood ceremonies is such that the person uninitiated is invested with complete social obloquy. A child is also in an ignominious position until this event. Although socialization is fundamentally a gradual, cumulative affair, the accession to social maturity in primitive society is conceived as climactic and abrupt. The past of the individual is considered to be cut off and during the course of initiation an exceptional, marginal environment is staged in which he is outside the normal life. In this period, called *rite de passage* (to use van Gennep's term), the ordinary cement of society crumbles—license, theft, arson, violence are often allowed. Promiscuous sexual intercourse is allowed the novices among the Papuans; even the conversation of the Kaffir boys may be of a dubious nature to show that shame no longer exists; moreover they are allowed to rob gardens and kill cattle with impunity. Among the Nandi of East Africa the novices are given purges and have their heads shaved; among the Indians of Virginia it was the custom to give them emetics "whereby remembrance of the past is obliterated." Among the Xosa of South Africa clothes, which are a social asset, are discarded and ordinary speech inverted. These measures heighten the sense of a break from the past, which is often reenforced by taking the neophytes by simulated violence from the company of the women. A strict regime of secrecy surrounds the rites, and as the candidate emerges it is believed that a rebirth has occurred. In the sociological sense this designation is justified, since with new costume (including such tribal mutilations as circumcision) and a new name the objective evidences of the new personality indicate a complete severance with the futility of childhood.

Most abiding in the metamorphosis wrought on the initiate is the strenuous inculcation of the pattern of sentiments and behavior which, it is thought, best promotes tribal solidarity and prosperity. The initiation thus serves as the chief vehicle to link generations in the transmission of the culture complex. The individual is now an active contributor to the food supply, a family head and a cult participant; he is in intimate association with the ancestral glories of his tribe—a complete and full fledged tribesfellow. Of these various duties food getting is the prime concern. The series of abstentions, fasts and privations ceremonially undergone, as, for example, in the Adaman Islands, is intended to develop the realization that not only the power to obtain food but also the right to use it without danger is

something that one owes to society and that its bestowal involves acceptance of the corresponding obligation to share the catch or yield with one's fellows. Other customary outward marks of affiliation, such as dress, are assumed for the first time; and the right to other pleasurable activities, such as smoking and drinking, are conferred. Usually the primitive educational system is climaxed in the didactic tactics of the initiation: law, morality, tradition, hygiene and cult focus in a varying degree of agglomeration compose the curriculum offered in the initiation bush or hut.

Through all initiation exercises there is set up an atmosphere of continuous excitement, novelty and tumult that is intended to enlist the fervent interest of the youth. Put on edge through ingenious torments, sleeplessness and nerve racking frights, the candidate becomes keenly sensitive to the power of his preceptors and indelible, life long impressions are made. The technique is illustrated among the Bechuanas, where the boys in a state of nudity engage in a dance during which the men of the village pummel them with long, supple wands while asking them questions such as "Will you guard the chief well?" "Will you herd the cattle well?" In this way is enforced the sentiment that success rests in conformity—and power in the hands of the elders. Those who wince or demur or who cannot pay the necessary fee are killed or declassified for life.

Initiation rites in the more complex, historical cultures are generally assumed to be functions of specific institutions or subgroups rather than of the folk as a unit, largely since the employment of written language makes possible the use of more consecutive pedagogical devices of less spectacular nature. To custodians of the cult and to professionalized religious groups particularly pass the functions designed as means for the transmission of the general power of social bonds—a mystification or abstraction of the cohesion required to maintain the existing social order. Active participation in the organized religions requires passage through the ceremony of Communion or confirmation in Christian churches and that of the *bar-mitzvah* in traditional Judaism, ceremonies which have absorbed much of the solemnity and ritual of pagan rites. With the greater economic potency of private property, chattels, slavery and the like there arise the invidious interests of the aged, the men and the professional groups, which can be enforced or shared only through the medium of

surrounding entrance rites with an aura of secrecy. Thus investiture with the trade and professional secrets in the guilds of the Middle Ages took on the proportions of esoteric ceremony akin to the magical regeneration crisis occurring when the neophytes were admitted into the Greek mystery cults. Many religious and trade groups adopted the esoteric tradition of puberty as a protection against penetration or for survival, since the *sacralia* are revealed only on this occasion to the initiated. In recent and contemporary society initiation and entrance ceremonies often acquire the air of incongruity or buffoonery as anachronisms in their use by fraternal societies, clubs, universities, subversive political movements and the like. Yet the common thread essentially characteristic of all types of initiation lies in the integrative and subordinating tendency of a social group to draw its members into a workable unity—a unity continually threatened by youth or alien.

INITIATIVE AND REFERENDUM. The initiative is a device by which any person or group of persons may draft a proposed ordinance, law or constitutional amendment and by securing in its behalf a designated number of signatures may require that such proposal be submitted to the voters for their acceptance or rejection. The referendum, on the other hand, is an arrangement whereby any measure which has been passed by a city council or state legislature may under certain circumstances be withheld from going into force until the voters have had an opportunity to render their decision upon it. Thus the initiative and referendum logically go together and supplement each other. They were

grouped with the recall (*q.v.*) of public officials in the movement in the early part of the twentieth century for "more democracy to cure the ills of democracy."

The initiative and referendum are by no means new features in the mechanism of popular government. All ancient democracy was direct democracy. In the Greek city-states all legislation was initiated by the people and authorized by direct popular vote without the intervention of representatives. In the cantons of the Swiss republic the initiative and referendum have had a virtually continuous history from earliest times down to the present day. Even in the United States the initiative and referendum are among the oldest of native institutions. The initiative, for example, was given recognition in 1777 in the first constitution of the state of Georgia, which bestowed upon the people the exclusive right to propose constitutional changes. The referendum was brought into use before the adoption of the earliest American state constitutions and has been compulsory in the process of constitutional amendment in practically all states ever since.

But the use of the initiative and referendum in the process of ordinary lawmaking is a relatively modern development in the United States, although sporadic examples may be found in various states during the latter half of the nineteenth century. More particularly the referendum was used as a means of expressing the direct voice of the people in certain localities on such matters as bond issues and the sale of intoxicating liquors. Not infrequently moreover state legislatures and city councils referred to the people some other controversial matters upon which they could not themselves agree.

Not until the closing years of the nineteenth century, however, did any American state authorize the use of the initiative and referendum as regular instruments for the making of ordinary laws. This first step was taken in South Dakota in 1898; Utah followed in 1900, Oregon in 1902 and seventeen other states during the ensuing three decades. Two other states have adopted the referendum but not the initiative.

The chief reason for the spread of direct legislation in the United States is to be found in the impatience of the people with the work of their state legislatures. By reason of the lack of authoritative leadership, the persistent lobbying on the part of special interests and the intermittent control of legislative bodies by political bosses a great deal of dissatisfaction with the work of

these legislatures developed during the closing years of the nineteenth century. People came to the conclusion that by their own direct action they could hardly do worse and might do better. Consequently they took into their own hands the power to make and to reject laws—not as a procedure for everyday use, but merely as a method to be used when the desired results could not be had in any other way.

The first step in the exercise of the popular initiative is the framing of a proposed ordinance, law or constitutional amendment. This is usually undertaken by some organization. Then it becomes necessary to secure a designated number of signatures in support of the proposal. From 5 to 8 percent of the qualified voters is the usual requirement. The petition is then submitted to some designated public official, who checks the names and if he finds them sufficient makes out a certificate to that effect. After this the measure is placed on the ballot, usually in abbreviated form or by title, and the voters record their decision upon it at the next regular election or at a special election called for the purpose. When a measure has been adopted by the people in this way it cannot ordinarily be amended or repealed by any action of the legislature. Generally speaking, the referendum follows the same general lines, except that the petition merely demands that a particular measure passed by the legislative body be submitted to the whole electorate before being put into effect.

Both initiative and referendum have been widely used by municipalities and by states, especially in the western part of the country, during the past thirty years. Sometimes as many as thirty questions have been placed on the ballot for decision by the voters at a regular state election. These proposals have been of every type, ranging from matters of fundamental policy to altogether trivial issues, from the levying of a state income tax down to the length of the luncheon hour in a city's fire department.

This submission is usually accompanied by a flood of propaganda on the part of the interested groups. It was anticipated that individual voters would study the various questions, make up their minds and cast their votes accordingly. To some extent the voters do this, especially when only a few questions are submitted; but with twenty or thirty questions on the ballot the great mass of the voters either follow the advice of some organization or are influenced by the advertising campaign. It has been demonstrated that a sufficiently vigorous publicity campaign

can usually encompass the adoption or defeat of any measure in which the people do not feel that they have a definite interest.

In practise moreover direct legislation has proved to be lawmaking by a minority. On the average not more than 80 percent of those registered vote on election day, and the proportion is usually much smaller. Moreover many of those who vote give all their attention to candidates and do not concern themselves with the questions on the ballot. Hence measures are sometimes adopted or defeated at the polls by only 25 or 30 percent of the whole electorate.

The adoption of the initiative and referendum was urged a quarter of a century ago by the progressive elements, who took for granted that if the people were allowed to legislate directly they would give their assent to progressive measures. On this basis the conservatives fought the movement in its early stages, while liberals welcomed the initiative and referendum as weapons with which to curtail the political power of the vested interests. But direct legislation has not proved to be revolutionary; on the contrary, it has been at least of equal value as a bulwark of conservatism. Voters in American cities and states have not hesitated to reject proposals for adopting the single tax or undertaking municipal ownership of public utilities, for giving pensions to city employees or imposing progressive income taxes. The use of the initiative and referendum appears to be slowly but steadily lessening in the United States. This may be a symptom of declining faith in political democracy and of increasing interest in some form of pluralism.

A part of the same progressive movement and closely related to the referendum was the demand for the recall of judicial decisions advocated by Roosevelt in his campaign of 1912 and adopted by Colorado in the same year. Under this proposal judicial decisions declaring invalid laws passed by the state legislature would be subjected to popular vote under conditions similar to those set forth for the legislative referendum. If a majority of those voting upheld the law, it would become valid despite the decision of the court. The movement made no headway and the Colorado provision was never invoked.

Outside of the United States the initiative and referendum have been used most frequently and effectively in Switzerland. There too, however, the response of the voters has almost uniformly been less than in the choice of parliamentary representatives. The average vote at initiative and referendum elections has been slightly less

than three fourths of the average vote at elections for the National Council, although it has on one occasion gone above the latter average. As in the United States, the effect of direct legislation has been slightly conservative.

Direct legislation was accorded a great deal of favor in the democratic post-war constitutions of European countries. Germany adopted the initiative and the referendum for the country as a whole, the largest political unit to attempt their use; they were also adopted by the German *Länder*. The adoption of direct legislation in the post-war constitutions was characterized by a number of innovations. Most interesting of these were the powers given the president and one third of the lower house in connection with the referendum; the use of the referendum to decide deadlocks between the two houses; the automatic dissolution of the Estonian Seimas following a popular vote contrary to the vote of the Seimas on a particular measure; and the German provision that an absolute majority of the qualified voters is needed to carry a referendum proposal involving constitutional questions and that a majority of the qualified voters must vote in any referendum in order to make its results valid. The complications resulting from these variations have militated against the practical utility of the initiative and the referendum. In actual practise they have been employed to a very slight extent in these countries, even less than in the United States.

INJUNCTION. This very effective judicial order usually commands a party to a suit and if necessary commands his associates to refrain from action which the court considers to be wrongful or a hindrance to the attainment of justice. Less frequently it commands the performance of acts conducive to justice. Disobedience to the injunction is contempt of court, punishable by imprisonment or other severe penalties. With rare exceptions all questions as to the issue of the injunction and disobedience thereof are decided by a court without a jury.

Injunctions originated in the English Court of Chancery. Requests for them by litigants indicate that they were granted as early as 1400. Several injunctions are recorded during the fifteenth century, but the first of which the text is extant dates from 1483 (1 Cal. Ch. cxiii).

The sources from which the chancellor derived the injunction are obscure. Although several writers have emphasized the resemblance of its language to the Roman law interdict, the methods of enforcing the latter were very different and much feebler. Any direct imitation of the interdict by the chancellors is unproved and improbable, but the interdict had a remote influence through its long development in the canon law. The ecclesiastical interdict forbidding religious services in a particular place offers a much closer analogy to the injunction. The canon law recognized other forms of orders forbidding specified acts, and since the chancellors were almost invariably churchmen until the sixteenth century they would very naturally apply in civil litigation a type of remedy which had been found effective in ecclesiastical controversies. A second probable source was the procedure of the common law courts. For nearly two centuries before the earliest indication of injunctions in Chancery the writ of prohibition had issued against waste—injuries to land by tenants. This writ sometimes differed from the injunction in that the order was directed not to the defendant but to the sheriff, who could take a *posse comitatus* and stop the waste. Many other types of wrongs were subject to prohibitions and subsequently, like waste, to injunctions. A third probable source lay in other proceedings in Chancery itself. For instance, subpoenas issued at the start of an equity suit commanded the defendant under a penalty to appear and answer the bill. It was only a step to impose a penalty for failure to obey some other command of the chancellor during the course of the suit. It is significant that injunctions apparently began

about thirty years after the earliest subpoenas.

The early chancellors were bound to no rigid and settled procedure. They were looking about for any remedy that might prove effective. This experimental attitude is illustrated by a Chancery suit about 1400 (Selden Society Publications, vol. x, Sel. Cas. in Ch., no. 70) asking for a writ directed to the sheriff and justices of the peace commanding them to order the defendants to allow the plaintiff to occupy his land without disturbance—a counterpart of the common law writ of prohibition. In another suit the chancellor might dispense with the officials as intermediaries and address the writ to the defendants themselves—a true injunction. This makes it even clearer that the injunction was a natural development of methods of enforcing obedience which were in use in England in the fourteenth century.

The subsequent history of the injunction is bound up with the general history of equity. As the equitable jurisdiction of Chancery spread over new fields, the scope of the injunction correspondingly widened, for it was one of the most powerful weapons for carrying out the chancellor's determination of rights. Resort to the injunction was also stimulated by the gradual disappearance of prohibitions and other preventive common law remedies which proved unsuited to the mechanism of trial by jury. Until 1700 injunctions were likely to be used for two main purposes. First, they protected interests in land, then the chief form of property, although some cases involved chattels like title deeds, jewelry and heirlooms. Secondly, legal proceedings or judgments founded on unjust grounds were frequently enjoined by the chancellor, who thus corrected the defects of the common law courts, a practise which aroused the resentment of the law judges and culminated in the famous controversy between Coke and Ellesmere. Thenceforth if the rules of equity conflicted with those of the common law, the injunction enabled the rules of equity to prevail. The growth of business in the eighteenth and nineteenth centuries led to new types of private wrongs for which the injunction was needed. It was also employed against public nuisances as urban congestion rendered these more numerous and more injurious. With the disappearance of separate courts of equity in England and most of the United States and the consolidation of legal and equitable powers in the same courts, all trial judges (except those in petty courts) acquired the power to grant injunctions. But the constitutional guaranty of a

jury trial does not apply to injunction proceedings, for it was not customary in equity courts when the constitutions were adopted.

Injunctions are classified chronologically into *ex parte* restraining orders, temporary injunctions and permanent injunctions. These may be conveniently discussed in reverse order. Permanent injunctions are granted at the end of a suit after both sides have fully presented their evidence and the case has been decided on the merits. Temporary (or interlocutory) injunctions are granted during the course of the suit and framed to prevent acts which might prejudice its final results. Sometimes such injunctions are said to preserve the status quo, but this does not necessarily mean the maintenance of the existing situation without change. The phrase merely describes the situation which the court thinks it just to maintain until the merits have been decided. Temporary injunctions are issued after notice to the defendant and a brief opportunity for both sides to present evidence and arguments, but without the fulness required for permanent injunctions. They may also be dissolved before the final decree if the defendant shows that they were improperly issued or have become undesirable. The plaintiff is frequently required as a condition of temporary relief to give bond. *Ex parte* restraining orders resemble temporary injunctions and are frequently called by the same name; but they are issued at the outset of a suit on the basis of proof presented by the plaintiff alone in the form of affidavits or oral testimony, without any chance for the defendant to be heard or to cross examine. This drastic remedy should be given only on a showing of great urgency, and the defendant should be afforded an early opportunity to attempt to vacate or modify the order.

Injunctions are also classified according to their form, as prohibitory (negative) and mandatory (affirmative). Since the very numerous simple affirmative orders to sign deeds, pay money and the like are not called injunctions, the term mandatory injunction is applied only to orders for the performance of more complex or unusual acts, and such orders are much less frequent than prohibitory injunctions. A century ago mandatory injunctions were theoretically regarded as improper, although they had been granted in several early cases. Defendants, however, were in effect required to perform affirmative acts through the ingenious but not ingenuous method of negative language forbidding them to allow the existing situation to continue.

Thus if a defendant had wrongfully cut a doorway in the plaintiff's brick wall, the court would enjoin him from permitting the opening to remain. The English judges have now repudiated these roundabout methods. During the nineteenth century courts were especially hostile to mandatory injunctions ordering the construction of a building, the operation of a railroad and other detailed or prolonged activities, but they are now increasingly ready to regard such objections as merely a factor to be weighed against the hardship upon the plaintiff if left to his action for damages. As Judge Hough has said, "The tendency of the times is to 'take on' harder and longer jobs" [*Kearns-Gorsuch Bottle Co. v. Hartford-Fairmont Co.*, 1 Fed., 2nd, 318 (1921)]. Mandatory injunctions are usually permanent, because it would be harsh in most cases to make a defendant perform elaborate and expensive acts to which the plaintiff may prove in the end not to be entitled.

The definiteness of injunctions varies greatly with different judges. Some use general terms, such as forbidding any acts which operate "to the injury of the plaintiff" or "render his premises unfit for use and enjoyment as a residence by reasonable and normal persons." The defendant is thus left to ascertain for himself "how near he may with safety drive to the edge of the precipice, and whether it be not better for him to keep as far from it as possible" [*Charles E. Hires Co. v. Consumers' Co.*, 100 Fed. 809 (1900)]. A preferable view is that an injunction is analogous to a criminal statute and ought to be equally definite and clear in its terms; when practicable it should discriminate carefully between the acts which are lawful for the defendant and those which are unlawful [*Collins v. Wayne Iron Works*, 227 Pa. 326 (1910)]. An unlearned man should be able to understand it without employing counsel. Flexible decrees may also be framed directing the use of remedial devices with the hope that they will end the injury and at the same time avoid the necessity of closing down the defendant's business until he has had an opportunity for installing and testing such devices. Meanwhile the case can be kept open for further action after the results of experimentation have been ascertained. Unlike a judgment for damages, which is necessarily simple and final, an injunction can contain many qualifications adapted to the facts and can be modified from time to time if changes are made desirable by new evidence or new conditions. This flexibility renders the injunction an ad-

mirable instrument for judicial handling of the complexities of modern life.

Injunctions are applied in a great variety of well settled situations. In connection with the specific performance (*q.v.*) of contracts both mandatory and prohibitory injunctions may be issued. The commonest use is against torts injuring real and personal property and various intangible business rights. A threatened or existing wrong will ordinarily be enjoined if the legal remedy (an action for damages) is inadequate. For instance, the defendant threatens to destroy a grove of oaks, which no money damages could replace. The prevention of "irreparable injury" is sometimes stated to be an indispensable requisite for injunctions, but this is true only if the phrase is understood in a loose sense to include situations where the legal remedy is inadequate for other reasons besides the impossibility of physical replacement. Thus an injunction may be granted when the defendant is insolvent, so that a judgment at law would be worthless; or when the extent of the prospective injury to the plaintiff's business could not be accurately measured by a jury; or when the defendant threatens a long series of wrongs which would lead to a vexatious multiplicity of suits. Likewise in many cases not involving torts the injunction may be used to obtain joinder of causes of action growing out of the same transaction.

Other acts enjoined include breaches of trust, improper foreclosures and judicial sales, the exercise of eminent domain powers before compensation to the owner is paid or secured and (in some states) the enforcement of illegal taxes. Partners can enjoin improper uses of the firm property; stockholders sometimes have a similar remedy against waste of the corporate assets and other wrongful acts by officers and directors; taxpayers can prevent the unlawful expenditure of public money.

The frequent assertion that injunctions will not issue to protect interests of personality, like reputation or freedom from bodily restraints and mental annoyances, rests on no principle of justice. Indeed the injunction is much better adapted than the jury action for damages to deal satisfactorily with some subtle injuries, such as a series of insulting letters persistently sent to a nervous person. Recent courts have been increasingly willing to enjoin wrongs to personality. Each type of such injuries, however, presents special considerations which ought to make a judge cautious in granting relief. For instance, it is doubtful whether an injunction can practically

succeed in terminating the illicit association of a plaintiff's wife or daughter with her paramour. Again, improper expulsions of members of clubs, churches and other associations injure the member's personal enjoyment and standing in the community; but indiscriminate judicial interference by injunction or mandamus (*q.v.*) with the internal affairs of these associations may cause objectionable results.

The desirability of the injunction for dealing with numerous civil wrongs is generally recognized, but serious doubts have been aroused by its rapidly extending use in the United States for two other purposes—checking activities which might be prosecuted criminally and upsetting administrative orders and decisions.

Since the 1890's the injunction has been increasingly employed in the United States as a substitute for criminal proceedings. The situation recalls the Wars of the Roses, when criminals were brought to justice in Chancery because the law courts were helpless to cope with the widespread disorders of the time and judges and juries were cowed or corrupted by powerful offenders. But since 1500 crimes as such have had to be established in the criminal courts, where the accused has a right to trial by jury. However, additional factors of an equitable nature might bring some criminal acts within the scope of injunctive relief. For example, a threatened criminal act might also be a private wrong which would cause irreparable injury to property; then the owner could enjoin the act regardless of its criminal aspects. This principle, occasionally used for centuries, has become very important within the last few decades, because upon it rests the frequent issue of labor injunctions (*q.v.*).

Another long established principle allowed the attorney general or other official to enjoin as well as prosecute public nuisances, like a highway obstruction, a chemical factory spreading poisonous fumes and other structures which constituted a source of continuing injury to the public health and convenience. This power has likewise been much enlarged of late through legislation or judicial decisions bringing many additional crimes under the head of public nuisances. Prosecutors have used the injunction to break up prize fights, gambling dens, red light districts and illegal saloons. The Volstead Act and other statutes against liquor selling authorize "padlock injunctions." Many vice and liquor laws allow these injunctions to be obtained by a group of neighboring taxpayers when the district at-

torney takes no action because he is too busy or lazy or he is too tolerant or friendly to the lawbreakers.

How far can criminal acts be removed from the constitutional guaranty of a jury trial by the simple process of labeling them public nuisances? Conservative judges and writers would limit the extension to crimes which roughly resemble the older types of such nuisances and they insist that the so-called nuisance must possess a local habitation of some permanence, from which disorders and public annoyances radiate and which can serve as the focus of the attack by the injunction. A more radical view dispenses with these requisites and allows the public prosecutor to enjoin unlocalized groups of persons from continuing alleged illegal activities, such as large strikes or criminal syndicalism. An occasional syndicalism statute, as in New Hampshire, expressly authorizes such injunctions; but Kansas and California judges have endeavored to break up the Industrial Workers of the World by blanket injunctions without any legislative sanction other than the statutory creation of this new crime.

This resort by public officials to the injunction to stop illegal establishments and revolutionary organizations is defended on several grounds. Public safety is then much more surely and rapidly maintained than by criminal proceedings. The police will not arrest for some of these offenses, and juries will not convict. In any case a jury trial means delay, and the grand jury where still required adds another burden. In a criminal trial the defendant's guilt must be proved beyond a reasonable doubt, while a padlock injunction or a jail sentence for contempt can be obtained on a bare preponderance of the evidence. Furthermore a prosecution cannot be brought until a crime has been committed, while an injunction can often forestall the offense and thus prevent any injury to the public. Finally, an injunction is sometimes more humane to defendants. If successfully prosecuted they will be punished for acts which perhaps they thought legal, whereas an injunction gets rid of the objectionable establishment without punishing individuals, so long as they obey the court order. An injunction tells the defendant exactly what he must not do and so serves as a much fairer warning than a general criminal statute, which men sometimes disobey without knowing it. This partial absence of the punitive element avoids the vindictive atmosphere surrounding a criminal trial and makes it easier to obtain a de-

cision in the state's favor. In short, injunctions are much more efficient than prosecutions.

These frequent public injunctions, however, against acts which were formerly prosecuted criminally raise grave objections. The accused is deprived of trial by jury and of all the normal safeguards of the criminal law. Even if the defendants are in fact lawbreakers, the community may gain less from the increased efficiency of the injunction than it loses from the resentment caused. The responsibility in criminal prosecutions is shared by the jury, but in these injunction suits it falls entirely upon the judge. The turning of equity judges into superpolicemen creates the risk of arousing a hostility which may eventually lead to drastic restrictions upon their powers, even over matters where equitable relief is badly needed for the accomplishment of justice. The breakdown of the criminal law in the United States is the real reason for the increasing use of the injunction against criminal activities. It would certainly be better to reorganize the administration of criminal justice than to continue to rely upon this substitute.

The injunction is also much used in the United States against the administrative acts of public officials, such as the collection of taxes, the regulation of business and the fixing of rates by public utility commissions. This injunctive relief is especially important when the constitutionality of the statutes under which the officials are acting is questioned. Although the plaintiff must allege the existence of some normal ground for equitable jurisdiction, such as multiplicity of suits or the probability of irreparable injury, the courts do not scrutinize these grounds closely. The real purpose of the injunction is to obtain a judicial review of the administrative order; and in some jurisdictions—for instance, the federal courts—it has become the regular method of accomplishing this result, which may be attained elsewhere by an entirely different procedure, like *certiorari* in New York. The injunction has the advantage of raising questions of the validity of administrative action at an early date, but it is absurd for one branch of the government to be trying to do something while another branch is exerting itself to prevent it. The process is like putting on the brake while the accelerator is pressed down. Additional objections arise when lower federal courts block state administrative bodies by this summary method, which although desired by plaintiffs may not be the wisest way of adjusting delicate conflicts between different parts of the federal system. Because of the readi-

ness with which single United States judges enjoined orders of the Interstate Commerce Commission or state commissions on constitutional grounds, a series of acts of Congress required three federal judges to participate in such action and imposed other restrictions (U. S. Code, tit. 28, sects. 47, 380). Perhaps a more straightforward method than the injunction for the judicial review of administrative decisions would be desirable in both state and federal courts.

The modern law of continental Europe has no precise counterpart to the injunction. Its work is performed by several different remedies. Unlawful acts are prevented by administrative orders and police action more than in the United States. The civil tribunals, which recognize no distinction between law and equity, enforce their judgments whenever possible by execution *in natura*, by which through the aid of officers comparable to sheriffs the plaintiff gets the very thing to which he is legally entitled instead of a money substitute, as in Anglo-American actions at law. A similar remedy in Anglo-American courts would often render injunctions needless. Interlocutory relief is less common than in Anglo-American law but can be obtained through attachment and other forms of summary procedure when speed is necessary. Since administrative decisions cannot be reviewed in the civil courts but only in administrative courts, anything resembling the injunction against official acts is naturally impossible.

INLAND WATERWAYS. See WATERWAYS, INLAND.

INNOCENT III (Lothar dei Conti) (1161-1216), pope from 1198. Innocent's activities as pope were largely concerned with the two problems of reviving and propagating the orthodox faith and firmly establishing the political power of the papacy. In connection with the first, his pontificate is famous for the Albigensian crusade, which he finally launched in 1207 as a last resort to extinguish that heresy; and for the fourth crusade to the East, which, after he had failed to divert it from Zara and Constantinople, brought him the glory as well as the responsibility of establishing the Latin rite in the western portion of the Eastern Empire. His management of the second problem marks one of the high points of papal influence over secular powers. The death of the Holy Roman emperor Henry VI in 1197 and the reaction against Henry's lieutenants in Italy allowed Innocent to assume shortly after his elevation a commanding position both in Germany, where the recognition of the future emperor depended upon his support, and in southern Italy and Sicily, where Henry's wife, Constance, became his vassal in order to secure protection for her son, the future Frederick II. In the matter of the vacant empire Innocent decided for reasons ultimately dictated by fear of the Hohenstaufens to support the Guelph candidate, Otto IV, against the two Hohenstaufens Philip of Swabia and Frederick. The reasons for his

decision he gave in his famous *Deliberatio* upon the courses open to him. In so intervening he provided the first legal basis for the papal right to confirm imperial elections, founding this right on the original transference of the empire by the papacy from the Greeks to the Germans. At the same time the eviction of the German governors from central Italy and Otto's oath never to unite central Italy with Sicily enabled Innocent to extend the Papal States to their widest boundaries. After 1204 he was complete master of Rome. He exercised feudal sovereignty over Portugal, over Aragon and, after he had broken down John's opposition, over England. He attached the Bulgaro-Wallachian kingdom to the Holy See. He intervened drastically in the affairs of the Scandinavian kingdom to support the local church reformers against King Sverre. With Philip Augustus of France he was never fully successful. In the face of the pope's exhortations and fulminations Philip refused for years to enter into conjugal relations with his lawful wife, Ingeborg. His great triumph came when the perfidy of the Guelph Otto IV forced Innocent to admit the correctness of Philip's view that Guelph domination in Germany was dangerous. Innocent had to excommunicate Otto and to secure his deposition by the princes and the election of the young Frederick as emperor. To end the trouble he had to organize Europe against the party which he had originally supported and to form a coalition with the Hohenstaufens and the French, which defeated Otto and his ally, King John, at Bouvines in 1214.

In the realm of political ideas Innocent III with his high yet cautious claims stands midway between Gregory VII and Boniface VIII. Christendom, he maintained, was not only a moral unity but a visible, concrete world state under clerical guidance; although it was governed by territorial rulers, yet each part and the whole must recognize the supremacy of the Roman See and the plenitude of power held by Peter's successor, the representative of Christ. But when he came to intervene in temporal matters Innocent cautiously limited himself to moral issues. He declared that he had no intention to pass judgment in matters of feudal custom (*judicare de feodo*) but only to decide cases of moral guilt (*decernere de peccato*), since it was his duty to snatch every Christian soul from mortal sin. His views on the relations between the civil and religious powers he further expressed in his decretal letter *Per venerabilem*, addressed to the count of Montpellier. No mediaeval pope has

had so strong a sense of responsibility for the moral welfare of Christendom. As a canonist he is of vital importance for his definition and classification of existing rules. His court formed a school of instruction for Christendom. In matters of detail his chief concern was for the purity of elections; for the integrity, discipline and educational standards of the clergy; for the conservation of church property; and for the unity of the faith on the basis of a dogma at once flexible and cautious. These matters were definitely provided for by the Lateran Council of 1215. As an administrator Innocent made important contributions to the organization of the papal chancery and to the development of the cursus. He also laid down rules for the detection of forgery. His pontificate saw a prodigious increase of the judicial and administrative business that came to the Holy See. He maintained touch with the various parts of Christendom through the system of legates so largely employed by Gregory VII. In contrast with the latter pontiff Innocent ranks as a diplomat and a business man rather than as a saint. But like the greatest administrators he never set the means before the goal. The assertion of the plenitude of power was for him an avenue to the salvation of souls—an end with which, as his letters and sermons show, he was constantly preoccupied.

INNOVATION. The changes or novelties of rites, techniques, customs, manners and mores which constitute innovation are usually thought

of as purposive. The actualities of the social process, however, do not validate this connotation. The attribution of intent is always retrospective. But the causes of innovation are too complex to be covered by merely personal intent. In so far as human existence is a process and not sheer repetition, the rise, the forms, the life cycles and the influence of innovations are the vital theme of history and the social sciences. Innovation includes in its range the transformations in food, clothing, shelter, defense against enemies and disease, tools and technologies of production and consumption, forms of play and sport, rituals and liturgies of religion, precedents of law, inventions in science and thought, styles and attitudes in literature and the arts. Every social institution is a field of innovation, no matter how conservative its intent and how standardized its techniques and procedures. The limit to innovation comes only at the point where the identity of an establishment itself is menaced.

Within this limit innovations may be numerous and rapid: the very individuality of the institution may consist in them. This is the case among the various divisions of science. The essential of each of these is the process of deliberate innovation which goes by the name of scientific method. Scientific method is simply another name for the gathering, testing and applying of innovations. How these innovations are reached is indifferent. Every innovation involves a certain contingency, a dimension of chance and luck; every innovation also begins as focal to some particular individual or very small group. Once a "scientific" mind has become aware of it, it is developed formally and tested experimentally, given its chance to succeed or fail. The work of breeders of animals, legumes, fruits; the invention and elaboration of machines; the transformations of the art of medicine in the last fifty years, in so far as these have anything deliberate in them, all rest on the presumption and use of scientific method. This is postulated wherever innovation is both deliberate and follows the gradients of social change. Where innovation is incongruous with those it must either struggle for its survival, establishing itself by means of a process of give and take with its environment, or be imposed by *force majeure*, as when after a revolution or a war the victor imposes upon the defeated a new way of doing or thinking.

Innovation may be slow or rapid, manifold or simple, but it is ineluctable. In a sense the mere lapse of time is innovating. Aging takes place in institutions and societies no less than in woods

and wines. This autogenous transformation through invariant repetition seems, however, never to occur in isolation. It is crossed and modified by other processes which add novelties *a priori*. Such are inventions, wars, crises and catastrophes, migrations, exhaustion of materials, exhaustion of interest (i.e. boredom). Boredom is a psychic force of innovation which deserves more attention than it has received. The revulsion which it generates and the subsequent searching and seeking are no small part of the dynamics of fashion, gaming, sport, crusades, exploration, scientific investigations and the like. All these involve contacts with changing environments, natural and human, osmosis or more violent impacts of cultures and consequent innovations.

The optimal conditions for innovation are a certain flexibility and readiness in the organic pattern of a society itself. These develop as a rule more easily in new societies, where a fresh start is being made; they develop also during a crisis such as a war, a profound business depression, a natural catastrophe or a revolution. At such times playing upon a ground of fear and uncertainty there is a feeling of the significance of the social adventure. Novelties are invited, projected and perhaps installed and domesticated; experiments are made and change may become a standard of public policy. Such was the case in Athens from the Persian wars through the Peloponnesian War and in the United States while the frontier lasted; it is now the case in Soviet Russia. Where custom coheres too firmly and authority is unshaken, the situation is reversed. In primitive societies the new way must be assimilated to the ways of the fathers before it can be accepted. Theocracies require that it shall confirm before it can be confirmed by the divine authority which they wield. Military or bureaucratic establishments reject it if it does not conform to the customary patterns and rituals of conduct. So does the institution of the law. In all these cases the variant is seen as a disorderly interruption of set routine and therefore *a priori* a heresy, a sedition and a danger. If its import is acknowledged and it is adopted it is usually denatured of all qualities inharmonious with the established procedure. Apparently only a crisis, the feeling of danger at hand, can transform this habitual inertia into a readiness to try new tools and ways. Thus the range and degree of international co-operation between the Allies during the World War, especially during 1917-18, have never been reached since and are being denounced in

peace by the very innovators who developed this cooperation during the war. Now in 1932 the whole world suffers because of the absence of this cooperation, which inherently would be far more competent in peace than in war. But now that the war crisis is over, the "elder statesmen" have relapsed into the elder ways. The peace crisis is insufficient to raise them out; and international cooperation, which goes inevitably with the diffusion of the industrial economy, is being held back by traditionalists in power anxious about the status quo of their rights and privileges. Should the crisis become profound enough, the innovation will be sped and facilitated.

Innovators are not necessarily rebels and the temper of innovation is not by any means the temper of revolt. Novelties, spontaneous deviations of the same energy, continually pour from the main stream of custom and convention. Thus the industrial revolution in England, the growth and diffusion of the factory system in the United States, in Germany and in Japan, took place mainly in the context of the old mores and on the initiative and by the effort of persons who were on the whole champions of those mores. Now the mores are being transformed and displaced by what they allowed. Again, the impact of photography and the theory of color vision on the painter's art constituted a fecundation of method and a diversion of ideals. The impressionists began by affirming the novelty and were forced into a defensive denying of the tradition. So-called modern movements are innovations only because of reaction against the innovation which photography itself represented. The intent of the post-impressionist schools was conservative; their achievements were innovations.

Nevertheless, innovators are forced into a combative position. For their novelties enter a social organization most of whose establishments are going concerns, and enter as competitors and deprecators of one or another. If they succeed in establishing themselves they become embodied in the organic flow of the mores. They cause that flow to deviate to a slightly different gradient definable by what they represent. This is what the city life of the Renaissance did to Christian society in Europe, what the fusion of the scientific with the technological attitude did to the eighteenth century mind and what the industrial system is doing to contemporary civilization. Of course there are programs of innovation whose dynamic is a reaction against the established order. Such programs sometimes function as

precipitates of deep lying emotions which are not disturbing enough to change the social order but do nourish a formulated opposition to it. The opposition becomes organized into cults and movements whose rituals and programs then identify it as a sort of antibody in the social organism. So Methodism grew to maturity in the Episcopal milieu of England. The single tax movement in the United States is such a development, and such also are cults of diet (like vegetarianism), of dress (like nudism), of health and of other goods of life. They arise as variants and survive as orderly antagonists within the nexus of the social process.

Since all innovations animate readjustments in the distribution and organization of social forces they automatically evoke the antagonism of those who are disturbed. If the antagonism is pervasive and deep, the innovation perforce lapses. If, however, it satisfies a want or nullifies an annoyance, however illusorily, it gathers a following. If the following comes from any top stratum of the community, from the prestige carriers, the innovation may win a great deal of superficial favor without modifying the basic social processes. It may become fashionable, like Christmas trees among Jews; like the consumption of yeast, liver, tomato juice and other dietary nostrums; like the recession of the corset and the spread of nudism; like the cult of patriotism and militarism among women claiming descent from revolutionary fathers. The scope and duration of the fashion vary with the amount of effort that the adoption of the novelty is likely to cost; the effort must not be very great in any event. If the innovation is relevant to deep lying discontents or to feelings of insecurity, then it may change the direction of an institutional process and break the fashion cycle altogether. Thus emulative realization of western attitudes and standards has the effect of displacing harakiri as a social procedure in Japan and face saving suicide in China; it has unveiled the women of Turkey and unbound Chinese ladies' feet; it has created the nationalisms of the Asiatic peoples and is profoundly transforming the pattern and goal of their civilizations.

Innovations are mostly resisted out of motives of self-interest and fear. The new is quite usually synonymous with the unreasonable, the dangerous, the impossible. As William James pointed out long ago, rationality is a sentiment in which the feeling of familiarity is fused with that of congruity with our fundamental hopes and desires. Sometimes mere familiarity may become

identical with this congruity. Thus people resist changing their dietary habits in spite of the fact that this change is required by health, the social setting or religion; there are freethinking Jews who get indigestion at the very thought of pork and "liberated" Hindus who are upset by the idea of meat. Between love of food and love of God or country the difference is in degree, not in kind. All involve clinging to the habitual, familiar and secure. When that is felt to be menaced, the opposition to innovation becomes fanatical, as may be observed in the attitude of so-called patriotic societies in the United States toward "socialism" and "Bolshevism." One of the most curious of phenomena is met when the proponents of an innovation that has reached the point of toleration turn upon those who propose a more extreme innovation in the same direction, as is often the case with the socialists and the communists. All these attitudes rest fundamentally on a sentiment combining fear and insecurity. But they become rationalized as "loyalty to the principles of the fathers," "rugged individualism," "you can't change human nature," and the rationalizations are elaborated into philosophic systems demonstrating the foregone conclusion. Such are the various philosophies of racial supremacy, cultural superiority and the like. Where innovations have finally established themselves and compel recognition they are assimilated to the old order or the old order is assimilated to them by means of some formula. Thus in the United States "trusts" were feared at their origin and laws were passed to constrain them. But they developed into the dominant controls of the economic process; the established order has to count with them and acquiesce in them. The Supreme Court of the United States celebrated this necessity by the well known decision concerning "the rule of reason" [Standard Oil Co. v. United States, 221 U. S. 1 (1911)], which has resulted in the virtual nullification of the original intent to control the trusts rigorously.

In the light of the foregoing the social position of an innovator is determined, other things being equal, by the success of his innovation. Persons like Edison, Einstein and Marconi have by no means entirely overcome the resistance to their respective innovations. But they are honored at home and abroad. If Jesus of Nazareth can be called an innovator, the same thing holds of Him. For His status in Europe changed with the coming to economic and political power of the priests of His cult. The same thing is true of Lenin both

in Russia and abroad and would be of Henry George if his program could be imposed at least as those of Christ and Lenin have been. If, however, an innovation fails to establish itself, its projector may be thrown into jail, like Roger Bacon, or live a despised outcast all his days. Social position for the innovator, as for everybody else, is a function of proved and acknowledged power.

INQUISITION. The Inquisition was the office of the mediaeval church for inquiry into heresy, which was commonly interpreted as obstinate adherence to opinions arbitrarily chosen in defiance of accepted ecclesiastical teaching and interpretation. It was an office not primarily of punishment but of examination and of instruction, and it attempted to secure the abjuration of their errors by the heretics whom it discovered. To a logical churchman of the time it represented the natural and merciful method of preventing the spread of doctrines which endangered the souls of all who heard as well as of all who communicated them.

In the eleventh and twelfth centuries popular frenzy against those who professed unorthodox opinions resulted in indiscriminate burnings of the suspected; their protection as well as their proper examination became necessary. In the absence of clear understandings as to the respective parts which the secular and ecclesiastical

authorities might play in the punishment of heretics the arrangements prevalent throughout Christendom were often the result of local agreements between the bishops and the king. In 1184 Lucius III and Frederick Barbarossa had arranged that the bishops should make the inquiry for heresies and excommunicate the heretics and that the secular arm should enforce the imperial ban of exile and undertake the destruction of suspected houses.

Decrees such as these were only spasmodically carried out, for as Catharism grew the problem became too general to be solved along local lines. The initial failure of Innocent III to convince the Albigensians by means of special missionaries, together with the crusade which in consequence he felt bound to undertake, made it clear that some more permanent prophylaxis was needed. This the normal canonical method of diocesan inquiry through the bishop was not strong enough to provide, since the bishop was a man of many duties and the task of discovering and examining heresy demanded both expert theological knowledge and an organized system of delation through trustworthy informers. The latter was to a certain extent constructed by the decrees of the Council of Verona, 1184, which directed that bishops in making periodical circuits of the dioceses for inquiries into heresy should compel trustworthy persons to denounce those who were *diffamati* for not living as good Catholics. The problem was how to secure the regular and effective body of witness of error, and for this task the ordinary church courts were just as inadequate as the special delegates sent by the papacy into disaffected areas.

Gregory IX organized these spasmodic efforts into a regular system. Permanent judges delegate were instituted to cooperate with the bishops in their inquiries. They were given power in 1233 to take action without appeal against all suspected persons and to call upon the secular arm to aid in their capture. The personnel of these judges came to be selected from the two mendicant orders. The preaching friars, or Dominicans, through the location of their early settlements and the personal character of their founder took the leading place in the new organization, but they divided their duties on a geographical basis with the Franciscans. Scandinavia was exempt from their activities and England, as will be shown, had no inquisitors other than the archbishops and their suffragans. Portugal did not receive the system till 1531.

The most threatening fourteenth century her-

esies prior to the spread of the doctrines of Wycliffe and Huss were the remains of Catharism in the south of France and the theories of the Waldensians, Beguines and pseudo-Apostles in northern Italy. In addition, the church was called upon to stamp out sorcery and witchcraft of various kinds and belief, such as that of Joan of Arc, in interior revelation from or communication or understanding with supernatural powers. The later Middle Ages witnessed the growth of heresy in two main directions: doctrines of internal illumination and extreme religious subjectivism, which are frequently the product of mystical enthusiasm; and the kindred notions, that of the absolute poverty of Christ—associated with the "spiritual" Franciscans—and that of clerical possessions as depending for their justification on the personal goodness of the possessor. The latter notion was the application to the clergy, particularly the religious orders, of Wycliffe's doctrine that lordship is founded upon grace. To this the English Lollards and a large section of the unorthodox Bohemians added erroneous opinions on the sacrament of the Eucharist. But although sacramental heresy was serious it was not so dangerous as a false ecclesiology, the main error which the later mediaeval church had to combat.

The method of procedure for inquisitors has been described by the Dominican Bernard Gui in the fifth part of his *Practica inquisitionis hereticæ pravitatis*, written in the early fourteenth century. The citation of the suspected person was made in his own house through the parish priest in the presence of witnesses and again on a Sunday or in certain cases on three consecutive Sundays or festivals. If the suspected person did not come within a year, the citation having been repeated, he was pronounced excommunicate. The alternative method of citation was the more stringent one of summary capture upon clerical request by the secular power. The inquisitor then interrogated the prisoner in the presence of two religious and a notary who took minutes of the questions and replies. There was no *libellus* presented as in ordinary canonical procedure. The inquisitor was instructed to make his inquiry simply and directly (*de plano*) and his powers were not subject to the territorial limits laid down in the thirty-seventh canon of the Fourth Lateran Council of 1215. No exemptions or appeals were permitted. Culpability was determined either by the confession of the victim under examination or by the evidence of witnesses, who for this purpose need not necessarily

be persons of unblemished character. Their depositions were communicated to the accused, but their names were kept secret and he was never confronted with them. Generally the inquisitor aimed at securing a personal confession, which might be effected by persuasion, accompanied where necessary by judiciously prolonged detention in prison.

In certain more obstinate cases the confession might be elicited by torture, as sanctioned by the bull *Ad exstirpanda* of Innocent IV. The period when torture seems to have been most employed is the fifteenth century in the great campaigns against witchcraft undertaken in southern Germany and in the district of Arras. The bull of Innocent VIII *Summis desiderantes* (1484) shows that a reaction had been taking place in the upper Rhineland against the rigorous method of the inquisitors. In 1522 the humanist J. L. Vives in his edition of the *De civitate Dei*, when commenting upon the ninth book, speaks of the evils of torture, which men preferred to death.

The sentence required the cooperation of the ecclesiastical ordinary and was generally given in an assembly of secular and religious clergy reenforced by lawyers. It could always be revoked or modified except where the accused was left to the secular arm for death by burning; and even here repentance *in extremis*, provided that the accused was prepared to abjure sincerely and denounce his errors and former accomplices, would justify the lay court in returning him to the inquisitor, in which case his punishment would be perpetual imprisonment. The penalty of the stake could not, however, be mitigated in the case of a relapsed heretic, although he was allowed to receive the sacraments of penance and the Eucharist if he was converted at the end.

In the case of others the penalty might be imprisonment either in more or less open confines (*muris largus*) or else in rigorous and solitary imprisonment (*muris strictus*); the wearing of a distinct mark upon the dress to indicate the brand of heresy; or pilgrimages to the greater or smaller shrines of Christendom. In the last case annual visits were often prescribed and the penitent was enjoined to hear mass and sermon in the church which he was compelled to visit and to offer a candle to the celebrating priest, by whom he was solemnly fustigated before proclaiming his offenses aloud to the assembled congregation. In other instances pecuniary penalties were inflicted. In Languedoc severe cases frequently involved confiscation of goods and the destruction of the heretic's dwelling. Of the

property so confiscated part went to the ruler, part to the church. These confiscations constituted one reason why the pursuit of heresy was to the advantage of the state; but in any case the secular authority never scrupled to put the heretic to death. The use of the stake was made general throughout the Germanic empire by Frederick II in 1238; it became customary in France under St. Louis.

Although there was no inquisitor appointed by papal authority in England, the procedure, resting in the first instance in the hands of the bishops, followed not dissimilar lines. The practice as it developed after the papal condemnation of Wycliffe's heresy was that the bishop made inquiries and with the help of the secular arm, if necessary, seized and examined the suspected persons. Abjuration was made in the first instance before the bishop, who prescribed the penalty, frequently that of imprisonment. Particularly bad cases, where the accused persons continued their errors after abjuration or where they were condemned for disseminating Lollard opinions by means of books and writings, might be referred to convocation. About 1400 and thereafter, probably as a result of the determined influence of Archbishop Arundel, all the leading heretics were brought by their diocesans to the provincial synod. According to the procedure governing such cases articles were first "objected" to the defendant and his replies noted; after this there followed an examination conducted by a tribunal consisting of the archbishop and members of each of the mendicant orders representing theological interests and of trained lawyers representing legal interests; at the end there was rehearsal of the points established and an exhortation by the archbishop to the accused person to abjure. In the event of abjuration the penalty was fixed by the archbishop in convocation and generally took the form of a public recantation of error and of imprisonment until the heretic could find sufficient security for his good behavior. In cases of obstinate persistence convocation relinquished the accused to the secular arm. The state bound itself to assist the church in its pursuit of Lollardry both by putting the heretic to death (statute *De heretico comburendo* of 1401) and by cooperating through its local officials in the inquiry for heretics (statute of Leicester, 1414). In a serious case involving a man of high standing, like Sir John Oldcastle, the king himself tried to exercise his influence.

The sinister reputation acquired by the Holy

Office was probably due to the great powers given to the inquisitor, by the subtle distinctions employed in grading the suspected person and by the actual horror of the burnings. But it must be remembered that the inquisitor was frequently assisted by *virī periti*, lawyers who could keep a watch upon proceedings and who would certainly prevent serious injustice being done. Furthermore there is reason to believe that the number of relaxations to the secular arm was not great. The destruction of the suspect was by no means the purpose of the tribunal. The church did not desire the death of the sinner, and the inquisitor's object was to instruct and convince those in error of the truth of its doctrines. Less favorable interpretations derive largely from the rigorous conduct of individual inquisitors, like Conrad of Marburg and Conrad Tors in Germany or Torquemada and Lucero in Spain. In sixteenth century Italy the Inquisition became notorious for the examinations to which it subjected a number of illustrious men of science and letters. By this time, however, its main work in the suppression of heresy was done.

The adaptability of inquisition procedure to political ends was first revealed in the program of Philippe le Bel and his shrewd legist, Guillaume de Nogaret, in fourteenth century France, and later by the popes in their attempts to consolidate their temporal power in Italy. This adaptation was effected most thoroughly in Renaissance Spain, where the Inquisition was organized in close cooperation with the Spanish monarchy as a piece of state machinery, designed to exterminate antimonarchical groups, primarily Jews and Moors, and to establish both in Spain and throughout the Spanish empire in the New World a homogeneous population with a unified nationalistic outlook. The fact that these methods tended to contribute instead to the subsequent decline of Spanish enterprise may be attributed in part to the extreme severity with which they were applied at home and in the colonies.

INSANITY

CRIMINAL LAW. In criminal cases the problem of insanity must be considered in three respects: first, as to the capacity of an accused person to be tried; second, as to the sanity of an accused person at the time of his offense; third, as to the procedure following acquittal on the ground of insanity.

The legal problem of insanity before or during trial does not involve the issue of responsibility or irresponsibility, which is based on the condition of the accused at the time of the offense, but so-called present insanity, i.e. mental incapacity for trial. Under early English law as in modern Anglo-American a man who becomes insane before arraignment or during trial is not obliged to plead to the offense or to stand trial provided he meets certain criteria, such as that he has not such "mind and discretion" as would enable him to appreciate the charge against him and the proceedings thereon or that he is not sane enough to recall the events of his life and to present to counsel the facts which ought to be stated to the jury. At common law the question of capacity to be tried was customarily settled by a separate jury, occasionally by personal inspection by the judge. Today the method for determining the condition of the accused before or after indictment or during trial varies. In some American states the court has discretion as to the means of inquiry, in others lunacy proceedings in chancery must be instituted; in some a jury trial is necessary, in others there is inquiry by two or more qualified physicians or by a commission of doctors and lawyers.

The chief weaknesses of these provisions are that since the initiation of the proceedings is left to persons untrained in psychiatry it becomes largely a matter of chance whether the defendant will be examined mentally before or during trial, unless his symptoms are striking, and that when an examination does take place it is not

always made by skilled experts. In Massachusetts under a unique provision of a law of 1921 (as variously amended in minor details) this situation has been remedied. A psychiatric examination by experts of the Department of Mental Diseases is a routine provision for all persons indicted for a felony who have been previously convicted of a felony or indicted for any other offense more than once. The objects of the examination are to determine the mental condition of the accused at the time of the examination and "the existence of any mental disease or defect which would affect . . . criminal responsibility." The report of such examination is not admissible as evidence in a case that goes to trial, and each side may still call its own experts; but in practise the neutral nature of the examination is relied upon to a considerable extent by courts, prosecutors and defense counsel, and "battles of experts," which so often mar the procedure in other jurisdictions, have in Massachusetts become practically unknown.

The most important aspect of the law of criminal insanity relates to the conditions under which the mentally ill are exempt from criminal responsibility. Some attempts to define these conditions were made as far back as the time of the Roman law as a result of the influence of the Greek physicians. A rescript cited in the Digest of Justinian (*Dig.* 1, 18, 14) dealt with the problem. The rescript states that the insane are irresponsible because they have been punished enough through their infirmity, that persons who are mentally ill may have "lucid intervals," that lack of knowledge of what one is doing may be a criterion of irresponsible insanity. Even the Germanic law sources of the Middle Ages, as is apparent from the various mirrors, town laws and customals, recognized the criminal irresponsibility of the insane. The Romanistic writers reintroduced the idea of the lucid interval, but Farinacius states that the majority of them indulged a presumption that the offense was committed during the ordinary state of insanity.

Among English legal commentators Bracton, Fitzherbert, Staunderforde, Coke, Hale and Hawkins attempted in various ways to evolve precise tests of irresponsibility. These, however, hardly amount to more than scraps of opinion. The Roman influence is particularly marked in Bracton. In *Rex v. Arnold* (16 How. St. Tr., 695), decided in 1724, a remark of Bracton's that an insane person is *non multum distat a brutis* turned up as the "wild beast test"; in *Hadfield's Case* (27 How. St. Tr., 1281), decided in 1800,

the brilliant advocate Erskine disposed of the views of Coke and Hale in insisting that "delusion, where there is no frenzy or raving madness, is the true character of insanity."

The modern English law rests upon the famous M'Naghten Case (10 Clark & Fin., 200), decided in 1843, in which the rules of responsibility were crystallized in the well known answers of the judges of England to certain questions propounded by the House of Lords as the result of an unpopular acquittal of M'Naghten, a paranoiac who killed Sir Robert Peel's secretary. The judges said that "to establish a defence on the ground of insanity, it must be clearly proved that, at the time of the committing of the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know he was doing what was wrong." This simple sounding "test" has in practise led to great confusion and difficulty of application; almost every phrase in the classic judicial utterance has been subjected to criticism from both a legal and a psychiatric point of view. The same is true of the further opinion of the judges in this case that a person who suffered from delusion might be liable to punishment if he knew that he was acting contrary to law.

Most American courts refuse to consider any criterion of the irresponsibility of the insane other than some local variation of the "nature-and-quality" or "right-and-wrong" test. In a number of jurisdictions, however, under the influence of both legal theory and medical attacks it has been held that irresponsibility may under certain conditions result from the presence of an "insane, irresistible impulse" even though knowledge of the nature and quality and wrongfulness of an act exists. The tests have been further complicated by the introduction in some American decisions of the element of delusion and its effect upon responsibility. The New Hampshire law expresses the doctrine that the question of irresponsibility by reason of insanity is altogether one of fact for the jury, since there is in truth no particular legal test which they must observe. Reviewing all the "symptoms, phases, or manifestations, of mental disease as legal tests of capacity to entertain a criminal intent," Judge Ladd in a well known case [*State v. Jones*, 50 N. H., 369, 398, 399 (1871)] concluded that "they are all clearly matters of evidence, to be weighed by the jury . . ."

In criticizing the tests of insanity it must be remembered that it has never been held that the mere existence of mental disease or defect in itself constitutes an exemption from criminal responsibility. One reason for this view is, as Kenny has said, that "lunatics are usually capable of being influenced by ordinary motives, such as the prospect of punishment; hence they usually plan their crimes with care, and take means to avoid detection" (*Outlines of Criminal Law*, p. 52). Nevertheless, a historical review of the subject indicates that the tests themselves, while remaining unchanged theoretically, have in practise gradually undergone modification not only to meet changing attitudes toward the objectives of punishment but to take account of refinements in medical knowledge.

The standard tests today proceed more or less upon the following assumptions, which are from the viewpoint of psychiatry questionable: first, that lack of knowledge of the "nature or quality" of an act (assuming the meaning of such terms to be clearly defined in the minds of juries and in judicial opinions), or incapacity to know right from wrong, is the sole or even the most important symptom of mental disorder; second, that such knowledge is the sole instigator and guide of conduct or at least the most important element therein and consequently should be the only criterion of responsibility when insanity is involved; and, third, that the capacity of knowing right from wrong can be completely intact and functioning perfectly even though a defendant is otherwise demonstrably of disordered mind.

The irresistible impulse test supplies in a measure the deficiencies of the knowledge tests; for it takes into account disturbances in the volitional inhibitory mode of mental life. It recognizes that although the disorder in the cognitive sphere may not be such as to prevent a defendant from having had some conception of the difference between right and wrong, he may nevertheless have been suffering from a deep seated mental disturbance which markedly affected his conduct. Emphasis of delusion as a test may be criticized in that it represents a singling out of but one symptom from a general disease pattern in the delusional mental disorders, a symptom which is not necessarily more important than the others.

All three concepts—knowledge, irresistible impulse and delusion—are subject to criticism as tests of irresponsibility because their employment neglects the fundamental theory of the

interdependence and interrelationship of mental processes; a disturbance in the cognitive, volitional or emotional sphere can hardly occur without affecting the personality as a whole and the conduct that flows from the personality. It could readily be shown that these outworn presuppositions may work injustice to offenders of various types of mental disorder, particularly those suffering from pronounced psychoneuroses, in whom unconscious motivation of conduct is believed to play a predominant role.

Several attempts have been made to remedy the situation. A distinguished legal and medical committee of the American Institute of Criminal Law and Criminology recommended in 1913 a test that was not really a test at all, for it was to the effect that no one should be held liable for a criminal act if his state of mind was such that he could not have had the necessary criminal intent—a proposition that is not of much practical value to a judge in charging a jury. A better attempt to overcome the dilemmas inherent in existing tests of irresponsibility was the earlier proposal of a committee of the New York State Bar Association, which in 1910 moved to abolish insanity as a defense to a charge of crime. This endeavor to eliminate the technicalities of the tests of irresponsibility at one stroke was accompanied by a provision that the court, if it believed the prisoner was insane or mentally defective at the time of the offense, might have an inquiry made and as the result thereof either impose the regular penalty or sentence him to confinement in an asylum for a term of years or life. Thus the effort was made to have the question of mental disorder considered, as certain criminologists feel it should be, not as a matter for the jury in its deliberations as to guilt or innocence but as a matter for the court aided by impartial experts in its deliberations as to sentence; this was essentially the principle behind a Washington statute which, not without room for doubt, was declared unconstitutional in *Strasburg v. State* [60 Washington, 106 (1910)] and a somewhat similar provision more recently invalidated in Mississippi [*Sinclair v. State*, 132 So., 581 (1931)].

While not much progress has been made with tests of insanity, it must be remembered that the consequences of conviction or acquittal on the ground of irresponsibility have in recent years been considerably modified in many jurisdictions. On the one hand, conviction today is not always or even often followed by the death penalty; on the other hand, acquittal frequently re-

sults in the defendant's commitment to a hospital for mental diseases instead of his release.

In the earliest English law insanity seems not to have operated as an acquittal, at least in murder, but to have resulted in a special verdict entitling the accused to a pardon. Subsequently in England and in a number of American jurisdictions if the accused was found irresponsible because of insanity he was not only acquitted but apparently no special order looking to his safety or to that of society was made. Under the English Criminal Lunatics Act of 1800 such a defendant was detained "during his Majesty's pleasure." In 1883 the Trial of Lunatics Act provided that upon an acquittal on the ground of insanity the jury should return a special verdict of "guilty, but insane," under which the acquitted person could be legally controlled by the home secretary. Under the Criminal Appeal Act of 1907 the Court of Criminal Appeal was empowered to quash the sentence of an appellant found guilty who was, however, in its opinion insane and to order the appellant to be confined as a "lunatic," as if a special verdict had been found under the 1883 act. The defendant is not released until the home secretary so decides.

In America practise varies. In one group of states the jury that acquits the defendant because of insane irresponsibility must state in one way or another whether it regards him as still insane; in other jurisdictions the jury must state whether it finds the defendant to be still dangerous; in several states the mental condition of the defendant at time of acquittal is determined by separate machinery.

The consequences of such findings vary. In a few states if the jury finds the defendant no longer insane or dangerous he is allowed to go free; in others when a jury acquits a person on the ground of insanity the statutes allow the trial court no discretion but to provide for his commitment with or without separate lunacy proceedings; in many states the court may, if it deems such a defendant dangerous, commit him to a hospital; in Massachusetts the court must order a defendant acquitted of murder or manslaughter because of insanity to be committed to a mental hospital "during his natural life."

A frequent remedy for release of persons incarcerated on the ground of irresponsibility is habeas corpus. The writ is used for this purpose in about a fourth of the states, while in the remainder special machinery for release is also provided. Whether the hearing on the return of the writ shall be with or without a jury also

varies from state to state; in some this matter is within the judge's discretion, in others within the petitioner's. In various states discharge from the hospital is within the discretion of the superintendent, commissioners of insanity, department of correction, trustees, special commission or a justice of the supreme court. In addition there exist of course the general provisions for commutation and pardon.

In recent years there has been an increasing demand for radical reorganization of the machinery of criminal justice. A plan has been frequently urged sharply to differentiate and specialize the two major processes of criminal justice—ascertainment of guilt and imposition of sentence. The decision as to the sentence, that is, the treatment of the offender found guilty, would in such a scheme be made by a tribunal specially qualified in the interpretation and evaluation of psychiatric, psychologic and sociologic data. The treatment originally imposed would be modifiable from time to time in the light of scientific reports of progress or retrogression of the offender. Certain procedural safeguards would protect him from possible arbitrary action on the part of the tribunal. A completely indeterminate sentence law, or at least one giving the tribunal wide administrative discretion as to the duration of the sentence, is an indispensable adjunct to such a system, as is also a scientifically manned clearing house and laboratory where offenders awaiting sentence would be given thorough observation and study. Finally, for the system to operate efficiently a thorough overhauling of existing treatment practises—probation, various forms of imprisonment, parole—would be necessary and there would have to be continuous experiments with new correctional and educative instruments. The result of this outlined system would be practically to eliminate the need of the cumbersome and unscientific defense of insanity, since the offender would as a matter of routine procedure be assured appropriate treatment regardless of whether or not the defense was resorted to. The clumsy device built up by the law for taking mental pathology into account in the determination of criminal responsibility would gradually become atrophied.

The continental law and practise with regard to criminal insanity are not significantly different from the Anglo-American. According to the German criminal code of 1871, "there is no punishable act, if at the time of its commission the actor was in a state of unconsciousness or of

marked disturbance of the mental faculties which excluded the free determination of his will." The French penal code of 1810 stipulates that "there is neither crime nor offense if the accused was in a state of mental alienation at the time of doing the act, or if he was constrained by a force which he could not resist." Generally the European codes take account of both the cognitive and the volitional elements in behavior and are broad enough to allow the trier of fact considerable scope for introducing "the human element in justice" in cases in which popular sympathy is with the accused. While the continental tests are subject to some of the same criticisms as Anglo-American tests, it should be noticed that the business of securing expert testimony is generally managed more rationally in European courts. Some European codes provide for "partial responsibility" and corresponding mitigation of punishment, but this is not true of the German or the French code. It is doubtless, however, possible for partial responsibility to be taken into account as an "extenuating circumstance." Most European codes also provide for measures of security against a person acquitted on the ground of insanity, but the provisions vary considerably.

SHELDON GLUECK

CIVIL LAW. In the civil law as in the criminal law mental incompetency of an individual leads to the extinction or diminution of his legal capacity to act and of his legal responsibility for his acts. The protection given the mentally incompetent in modern systems of law is limited by the protection accorded innocent persons who deal with him, hence the emphasis is placed upon preventive measures such as guardianship. The primitive superstition that the insane person was accursed by the gods or seized by evil spirits left no trace upon Roman private law, which as early as the Twelve Tables designated a familial curator for the *furiosus*, a lunatic who might or might not have lucid intervals, and an officially appointed guardian for other mental incompetents (*mente capti, insani*). The Roman law system has been adapted in modern European codes to a wider range of mental incompetency. Thus Germany and Switzerland have extended guardianship not only to prodigality, which was recognized in Roman law, but also to dipsomania and mental weakness, and the French civil code authorizes in case of prodigality or mental weakness the appointment of a judicial counselor whose consent is necessary to the

validity of certain types of transactions. A similar expansion of the concept of civil insanity as a ground for the appointment of a guardian has occurred in many Anglo-American jurisdictions, which by statute or judicial construction authorize the appointment of a guardian for a spendthrift, a habitual drunkard or even for a person likely to be imposed upon. Drug addicts are also frequently included. California and England are among the jurisdictions which have apparently gone furthest in this respect, while New York adheres more nearly to the narrower conception of early English law. In the latter system the king's prerogative of acting as guardian of the person and property of the mentally incompetent, however mercenary in its origin, came to be based upon the humanitarian conception that the king was *parens patriae*. To the lord chancellor was delegated at an early date the royal power to appoint guardians, and this function thus became a part of the jurisdiction of the Court of Chancery. In the United States courts of equity jurisdiction, adapting the powers of the English court, have ordinarily taken over this function, although by statute it has sometimes been conferred upon probate courts which have jurisdiction of decedents' estates.

While English and American judicial reports deal with many varieties of mental abnormality, legal tests of sanity do not conform to standards recognized by abnormal psychologists with educational or clinical objectives in view. The law has striven to establish flexible standards of incompetency. To deprive a man of his civil capacity or to relieve him of his civil responsibility to others calls for a more pronounced degree of mental abnormality (to say nothing of differences in type) than is requisite where the decision involves only specialized educational or clinical treatment. Other factors which have tended to maintain a relatively low legal standard of sanity are the emphasis upon freedom of alienation, judicial acceptance of the theory that mental faculties operate independently of one another and trial by jury. The frequency with which decisions of lower courts are reversed on appeal indicates the uncertainty of the legal standard.

Legal proceedings involving a determination of mental incompetency may be grouped into two main classes: preventive and restitutive. In the first group the issue is the competency of the individual for future conduct; in the second it is competency for a particular act already consummated, such as a conveyance, contract, will or

tort. In the former belongs the statutory proceeding to commit an insane person to a public or private institution for treatment and for confinement in the interests of the individual as well as of his relatives and the public. Although it resembles a criminal prosecution it is usually denominated a civil proceeding.

No person may be permanently restrained against his will except by due process of law. The safeguards of ordinary contentious litigation, designed for mentally competent litigants, are here inadequate; hence other safeguards are provided. The class of persons who may petition for commitment is restricted to near relatives or a public official, and in many jurisdictions the petition must be accompanied by the certificates of two qualified physicians. Notice must be given to the person alleged to be insane or to his near relatives, and a hearing is required. While trial by jury is not constitutionally requisite, in some states it may be demanded as of right and in others it is discretionary. Since propensity to do injury is the test in such proceedings, commitment does not preclude a finding that the individual remains competent for business transactions.

The other type of preventive proceeding is the appointment of a guardian (also called a committee, conservator or the like) of the property and person of an insane person. The test of sanity as usually formulated is a person's competency to manage himself or his affairs. The law thus emphasizes the intellectual process rather than the emotional basis of conduct. Yet in some jurisdictions the concept of incompetency is broad enough to include the emotional instability of old age and extreme susceptibility to imposition in business dealings. Lack of ordinary business judgment is not incompetency. The courts have felt that the denial of contractual freedom to a large portion of the adult population would seriously hamper economic intercourse. While guardianship of the person alone is still permissible, the proceeding is seldom resorted to where no property is at stake. The procedural safeguards in proceedings for the appointment of a guardian are much the same as in commitment proceedings, save that a jury trial is more commonly required. Unlike the Roman law, which effaced the juristic personality of an incompetent under guardianship (save during a lucid interval), American law limits the incapacity created by a judicial determination of insanity. The older doctrine that the contracts, conveyances and transactions of an incompetent

under guardianship were absolutely void has been shaken by more recent decisions holding that the appointment of a guardian merely raises a presumption of insanity, which may be rebutted by proving restoration of sanity and practical cessation of the guardianship. Notice of the guardianship is imputed to all persons dealing with the lunatic on the theory that the proceeding is one in rem.

The validity of a contract, conveyance, gift or other transaction may be questioned in a suit or by way of defense by the incompetent or his guardian or after his death by his heirs or representatives to set aside the transaction and obtain restitution of the status quo. Such a suit or defense may be maintained even though no prior adjudication of insanity has taken place. The test of competency is ability to understand the nature and consequences of the particular transaction at the time when it took place. The restitutive adjudication may seriously impair the interests of third parties, and the reported decisions show a tendency to apply a lower standard than would be applied in a guardianship inquisition. The policy of maintaining freedom of alienation excludes in most jurisdictions the mental weakness of old age and delusions on subjects not connected with the particular transaction. Transactions during a lucid interval are upheld, even though the individual has been confined to an asylum or has been suffering from delusions on unrelated subjects. Some courts, however, have set aside transfers of property because motivated by insane delusions, such as delusions of persecution [*Riggs v. American Tract Society*, 95 N. Y. 503 (1884)], thus shifting the emphasis from the intellectual to the emotional basis.

In most American jurisdictions transactions of insane persons are treated as "voidable" rather than "void." The legal consequences of this doctrine are that restitution of benefits received by the lunatic (or at least of those retained by him) is a prerequisite of his regaining that which he parted with, that innocent purchasers from the donee or the vendee are fully protected, that ratification after restoration to sanity validates the transaction and that the suit to regain land is tried in a juryless equity court. While very few American courts have gone as far as the more recent English decisions in enforcing the transactions of an incompetent in favor of a person who deals directly with him in actual ignorance of the insanity, the requirement of restitution often attains the same result by indirection. The

low standard of competency, excluding mental weakness or old age, is eked out by the Anglo-American doctrine of "undue influence," which permits cancellation of a conveyance or gift by a weak minded person to a domineering relative or confidant who by deception, threat or insistent suggestion knowingly took advantage of the other's weakness. Many of the undue influence cases involve controversies over the effects of senile dementia [McGregor v. Keun, 330 Ill. 106, 161 N. E. 99 (1928)].

Competency to execute a will may be determined in a contest over the probate of the will, in which trial by jury is the rule. The standard of competency is even lower than in transactions *inter vivos* because of the policy of upholding testamentary dispositions, especially where those persons are favored whom the court or jury regards as the natural objects of the testator's bounty. Some courts avowedly test the rationality of the testator partly by reference to the rationality of his testament. The mores of a testator's duties to his relatives thus exert influence under this guise.

An insane person, even one previously adjudicated to be incompetent, is civilly liable for his tortious injuries to the person or property of others. Although English law balks at imposing liability on one who did not understand the nature of his act, American courts award compensation to the injured person, partly in order to induce the lunatic's relatives to confine him and partly in order to discourage simulation. The ancient contention that the lunatic has no will ("Furiosi . . . nulla voluntas est," *Dig. L, 17, 40*) has not sufficed to protect him from liability for some wilful torts, such as assault and battery or defamation (on which authorities are divided), but has precluded liability for malicious prosecution and for punitive damages in any event. An insane person although not bound by his contracts is liable in quasi-contract to pay the reasonable value of necessities furnished him, for without the ability to obtain credit he would be left destitute.

Two standards of mental incompetency have struggled for recognition in the Anglo-American law of marriage. A marriage has been treated as the making of a civil bargain which can be annulled only upon proof that one of the parties was then incapable of understanding the immediate incidents of the relation; hence such ailments as feeble-mindedness, epilepsy, kleptomania and delusions are generally not grounds for annulment. Yet the eugenic standard of com-

petency has steadily gained recognition through legislation prohibiting the marriage of epileptics and others who though capable of understanding the legal consequences of a marriage are unfitted for its biological and social functions. The new standard is also recognized in judicial decisions [Gould v. Gould, 78 Conn. 242 (1905)] decreeing annulment or divorce on the authority of these statutes, although many of them are so loosely drafted as to be ineffective. Supervening insanity prolonged and incurable is a ground for divorce in a growing minority of American states: Alabama, Colorado, Connecticut, Idaho, Kansas, Minnesota, Nevada, North Dakota, Oregon, South Dakota, Utah, Vermont and Washington. Mental incompetency is also a disqualification for the acquisition of citizenship, for voting, for jury service and for holding public office.

INSPECTION. Inspection of commodities, buildings, industrial processes, trade practises and other phases of modern civilization by special employees of the government is merely one phase of law enforcement, conspicuous because governmental activity has penetrated into fields where common knowledge and chance report no longer furnish adequate information. In the collection of revenues, in which governments are always vitally interested, inspectors of a sort have been employed for as many centuries as customs, tolls, tributes and taxes have been exacted. Inspection and other aspects of enforcement are not in fact separable, for although in some instances inspectors merely publish their findings and the publicity itself acts as a corrective to illegal or undesirable practises, in others they are charged with the double duty of reporting infractions of the law and of bringing offenders to justice.

Supervision of commodities and of market practises by civil authorities is as ancient as the records. It was undertaken in Egypt, China, Greece and Rome. Mediaeval town authorities and later the wardens of craft guilds made particularly notable efforts to establish and uphold standards of quality, price and weight. The character of the supervision—inquiry into the accuracy of weights and measures or insistence that the producer place his mark upon the wares—as well as the severe punishments meted out to bakers whose bread was short in weight, to farmers who filled sacks with poor grain and sprinkled a little good grain at the top, to metal workers who used debased material in their wares, indicates the gravity of the offense of cheating. These regulations, like those of modern chambers of commerce and better business bureaus, protected not only the consumer but the business of more reputable interests against encroachment from less reputable. And although this supervision may often have been thought of as a desirable restriction of trade, it is clear that it must sometimes have been considered constructive promotion. Towns became important as trading centers; town officials would therefore wish to encourage legitimate trade. And as the records suggest that in proportion to the number

of sales cheating was extremely common, the mediaeval authorities met the situation by building up a body of specific regulations. Only when makers and sellers discovered that greater satisfaction of consumers' wants meant increased business did the early supervision and inspection by local authorities tend to become unnecessary and even troublesome. The growth in the volume of trade made the national governments which emerged in the following centuries increasingly aware of their dependence upon a sound economic life. In both England and France there were movements to nationalize the regulations protecting the quality of commodities, although the machinery for inspection remained local, exercised by wardens of crafts, clerks of the markets or special inspectors appointed by local justices. In France, where failure to develop large shipping interests made for greater dependence upon small but stable markets, high standards of production were insisted upon much longer than in England, where constant access to new markets opened up by explorers and traders soon shifted the emphasis from quality to quantity. The laissez faire movement matured there as a protest against the mass of restrictions and regulations which penalized producers and traders and impeded the expansion of competition based on rapidly changing methods of production. In country after country government supervision, which was by tradition specific and hence in a changing society restrictive, became less noticeably part of the economic life. But inspection was of course never completely abandoned. Even in America, where production took its own course more freely than elsewhere, certain standards were always insisted upon. The *Journal* of the New York state assembly for 1828, for instance, contains annual reports (submitted in accordance with statute) from inspectors in the cities of New York and Albany of fish, flour, sole leather, staves and heading, liver oil, potash and pearlash and lumber. Four standard grades of pine boards are listed in the report.

Now that quantity production has given rise to world wide competition for markets, uniform quality to insure liquidity has again become vital for the producing interests. Goods must be equally salable in Europe or South America, in six months' time or on twenty-four hours' notice. To a very great extent private interests in industry and commerce have brought about such uniformity as now exists—the machine technology is indeed responsible for much of

it—but here as elsewhere government has been pressed into service to control situations which private interest could not or would not supervise itself. Thus today there exist official inspection and grading of a wide variety of commodities for the domestic market or for export—grains, fruits, vegetables, dairy products, meat, ice, silk and so on through a long list. In recent years governments have somewhat increased their supervision over the conditions of fair competition through such organizations as the Federal Trade Commission in the United States. The use of unfair (substandard) marketing methods is discouraged not by systematic inspection but by special investigation of particular abuses in behalf of honest competitors, and legal proceedings are dropped against offenders who agree to desist.

The increasing complications of industrial society have led to governmental regulation of less tangible commodities. National banks are subject to inspection as part of the currency system; state banks and trust companies on the ground that they are of basic importance to the whole economic life. The extension of state activity to protect the savings of low income groups through supervision of savings bank investments, through regulation of building and loan associations and insurance companies and through the administration of blue sky laws is more definitely a limitation of private enterprise in the interest of certain classes of consumers. In the case of public utilities regulation of rates and services and of financial structure is justified on the legal ground that these industries are affected with a public interest. Supervision is accomplished by the requirement of standard accounting practices and similar devices for minimizing the work of inspectors rather than by positive control of operations. Logically, however, the suppression of fraud, the elimination of undue risk, the prohibition of undesirable trade practices and even such things as the age old supervision of weights and measures are simply necessary stages in the promotion of good business through the promotion of confidence.

Police power in its broadest sense—that is to say, the power of a state to act in the interests of the whole public and including, for example, the commerce power of the federal government of the United States—provides in theory the necessary authority for many types of regulation. But the most conspicuous exercise of police power in the modern state has come about through activities in behalf of public health, morals and safety.

The suppression of crime and the use of special officers of inspection for that purpose need no specific mention. Supervision of public health and safety is more characteristic of the modern age. A series of government functions were initiated by the humanitarian protestants against the abuses of the industrial revolution. Limitations on child labor in factories began in England early in the century; the act of 1833 (3 and 4 Will. IV, c. 103) stands out as the first factory legislation in any country to provide for national inspectors. On the continent governments interested themselves first in conditions of work, in special industrial hazards presented by the use of machinery and steam boilers and in safety appliances and only later in hours and wages of labor. Compulsory education and official interest in tenement house problems followed. Some pressure for housing reform in England came from overseers of the poor, but in regard to working conditions public opinion was only aroused to legislative action when strikes and drafts had called attention to the potential threat of poverty to the health and decency of the whole public.

Health services and regulations have grown most rapidly since the turn of the present century. The ancient standards of sanitation and building construction had disappeared in the dark ages. And even before scientists knew how diseases could be transmitted through polluted water supplies, communities again became aware of the need for pure water and were active in supplying it. When fires swept away towns, building and safety regulations were instituted. Other reforms followed. Meat, milk, food and drug, seed and fertilizer inspection; plant quarantines; periodic water analysis; smoke and light tests; sanitary inspection of bakeries, food factories, beauty parlors, dwelling houses and industrial plants; supervision of the manufacture of biological preparations; health examinations of school children and immigrants; enforcement of minimum standards of light and air in schools, homes and places of work; regulation of the use of fire apparatus and safety devices; inspection of elevators, ships, motor vehicles, airplanes and other dangerous inventions, these are only a few of the services instituted by governments, central or local, in the interest of public health or public safety. No adequate explanation can be offered of why the complete list of government inspection services includes the particular items which it does. Long as it is, it could obviously be much longer. The need for assistance in behalf of pub-

lic safety is felt more acutely than other needs, perhaps because dangerous technological inventions are more visible than changes in the distribution of industrial and financial power. Yet even here it would be difficult to say whether supervision had kept pace with the increase of danger. Regulation in behalf of consumers may have been retarded because of opposition by special business interests, or because public opinion has been so steeped in the doctrine that the promotion of good business is the promotion of the general good that it has not thought to notice how the people were faring. A great variety of influences have been at work and no single formula can describe them.

Growing up piecemeal, the administration of inspection services shows even more diversity than do the codes which they enforce. In every modern country there is some conflict of jurisdiction between local and central authorities. Inspection services traditionally in the hands of local authorities sometimes remain there after state or national laws are passed. In Germany the standards created by factory acts are national but factory inspection is left to the states. In the United States the health and safety standards themselves differ from state to state. Convenience of administration is sometimes sacrificed to tradition in these matters. In certain fields, however, as in building, the problem of control is essentially local, and city building and sanitary codes and inspection services frequently supersede the less rigid state requirements. As inspection grows more technical, division along functional lines is often made. Factory boiler inspectors cannot be charged with enforcement of the sanitary code, nor inspectors of electrical equipment with concern over the ages of child workers. Where inspection requires sampling and laboratory analysis, the field work may be in the hands of one group, technical work in those of another, while a third set of people concern themselves with the legal processes involved in enforcement. Different departments of a government may supervise precisely similar processes. The inspection in the United States of manufacturing establishments preparing biological medical materials for human consumption is the concern of the Public Health Service in the Treasury Department, and the inspection of such establishments preparing equivalent materials for use in animal diseases is the concern of the Department of Agriculture. Factory inspection in England is separate from mine inspection and from department store inspection, although

hours of labor and working conditions are the concern of each.

In effectiveness inspection services differ considerably. Even where statutes are relatively simple and specific and their enforcement somewhat removed from political and commercial pressure, there may still be difficulty in securing adequate personnel. Civil servants in Europe enjoy a prestige which is largely lacking in the United States and in consequence European factory inspection has been of higher grade than American. On the other hand, European trade unions maintain that their interests would be better served if workers received some of the higher appointments now reserved for experts. Inspection can rarely be either continuous or complete. Accordingly it will be most effective when enforcing such codes as building regulations, where one visit can certify lasting compliance with the laws, or when applied to such commodities as grain, where the smallest sampling will be representative of the whole. It will be least effective where conditions are so fluid that they can be altered or concealed while inspection takes place, a factor which for a long time made industrial inspection powerless and which still impedes banking and utility supervision. But even the most effective inspection may prove impotent when penalties for violation are incommensurate with the pecuniary gain.

The problem of administrative standards is fundamental. A striking difference between contemporary state regulations and those of post-mediaeval days is the large measure of administrative discretion now needed. Swift advances in knowledge of what constitutes purity in food or water or safety in transportation or construction make a large degree of elasticity in enforcement imperative. Furthermore modern legislators can seldom sift expert evidence sufficiently to be able to draft effective laws of the more specific type. Where standards are largely lacking, as, for example, in the case of biologicals, the government has been obliged to experiment in order to standardize materials. Safety standards in the United States are developed and assisted in operation by the Bureau of Mines, the Interstate Commerce Commission, the Bureau of Standards and the Public Health Service, by the various departments in all the separate states and by an almost indefinite number of trade associations, engineering societies and other private organizations exercising some degree of authority or control. The policing of standards already established may in such cases become less impor-

tant than activities leading to the formulation of new standards, and this has been the aim of European factory inspection. Even in the United States, where there is a strict theoretical separation of legislative, executive and judicial functions, it may conceivably happen that inspection activities, undertaken originally for purposes of enforcement, will furnish the necessary data for important and unheralded reforms. The widespread banking failures occurring in spite of supervision illustrate the weakness of a purely negative policy.

Inspection by the government in so far as it merely supplements the work of private interests is thus undertaken in a somewhat accidental number of unrelated fields as an aid to business and as a protection to the public. Essentially the same function is performed almost universally by industry itself. Every producer has his products "inspected" at some stage of the process, although the standards for acceptance or rejection may be extremely variable. Even public health and public safety are protected to a degree by inspections conducted by insurance companies, whose standards may be higher than the government minima. Whether or not government inspection services continue to increase in importance and elaborateness depends primarily upon how far the movement toward commercial standardization can go. Industries may succeed in imposing standards upon themselves without government intervention, as the cooperative marketing associations have already done. And, conversely, if all industry should be conducted by government, inspection as a separate and conspicuous phenomenon might disappear. Or the general enforcement of standards might even become a function of supreme control, as it has in Soviet Russia, where the Workers' and Peasants' Inspection checks the activities of other branches of the government.

INSTALMENT SELLING. An instalment sale, aside from a cash or down payment, is simply a credit or deferred payment transaction in contrast with a cash payment and does not differ in its nature from any other credit transaction. Instalment credit provides for the payment of goods in fixed instalments at stated intervals and in this respect it is a sort of funded debt in contrast with a demand obligation, which is payable at the request of the creditor, or the old fashioned book credit, which was payable in whole or in parts at the convenience of the debtor. It also stands in contrast with the kind of debt which runs for a stated period and which is to be paid in a lump sum at the end of the period. Instalment credit is protected by the commodity sold and is on the whole limited to goods with a resale value. The sales are usually conditional; the goods are delivered to the buyer, but the seller retains control over them; either the title remains in the seller and does not pass to the buyer until all the instalments are paid or the title passes immediately to the buyer and a chattel mortgage is given on the goods as security for the balance due. Default in payment usually gives the seller the right to repossess the goods; it also quite frequently forfeits all previously paid instalments.

Instalment buying is an old practise; it existed in ancient Rome, where houses were sold on time payments. But the practise did not assume importance until the period of capitalist production for widespread markets; it developed real significance only in industrialized countries during the nineteenth century and came increasingly into use in spite of a measure of disrepute attaching to it. As early as 125 years ago a furniture house in New York City was selling goods on time payments. Building and loan associations, which provide for the buying of houses on this plan, have been in existence for more than seventy-five years. The Singer Sewing Machine

Company has been doing a very profitable instalment business since 1856. There are also numerous piano and other musical instrument houses that have been selling in this way for the same length of time. McCormick reapers and binders have been sold on instalments almost from the beginning of their use. Books have probably been sold on time for a longer period than any of the commodities mentioned; all encyclopaedias, beginning with *Chambers's Encyclopaedia*, which appeared about 1750, have been sold on instalments. An extensive indirect form of instalment selling was the "credit check" system. The customer bought from organizations carrying on this kind of business a credit check for which he made a down payment and agreed to pay the balance at stated periods; the check was then used to buy goods (except food) at specified stores. The credit check system still prevails in England and Germany; in Australia the system, known as cash orders, flourishes alongside instalment selling.

Even though instalment selling similar to that which exists at the present time has been a common practise for the past fifty years or more, the growth of the system was not great until the last fifteen years, when it experienced an enormous expansion in both volume of sales and number of industries affected. About 1915 instalment selling was introduced into the automobile business in the United States, where it had a somewhat gradual growth for several years; after 1919 it suddenly expanded, reaching great volumes within a few years' time. In the industrial depression of 1920-21 the system spread to other lines of business and grew rapidly to large proportions.

Exclusive of houses, which are widely sold on instalments, it is variously estimated that from five to seven billion dollars' worth of goods were being thus sold at retail annually prior to the beginning of the depression in 1929. According to the Department of Commerce retail sales in the United States in 1929 amounted to \$50,000,000,000. On the basis of an estimate of \$6,000,000,000, instalment sales composed 12 percent of retail sales. It is commonly estimated that the amount of instalment debt outstanding at a given time was from \$2,225,000,000 to \$2,500,000,000, which is a more significant figure than the total of instalment sales over a period of one year's time. More than half the instalment debt outstanding is for automobiles; the next most important items are furniture, radios, clothing and sewing machines. It is estimated that 70 percent

of automobiles with respect to value is sold on instalments; 70 percent of household furniture; 80 percent of pianos; 80 percent of phonographs; 75 percent of radio sets; 90 percent of washing machines; 85 percent of vacuum cleaners; 90 percent of sewing machines; 70 percent of gas stoves; 90 percent of mechanical refrigerators; and 25 percent of jewelry. In 1927 approximately 27 percent of tractors and other farm machinery was sold on instalments (approximately \$100,000,000). In recent years there has been a considerable increase in instalment sales of clothing and jewelry. Instalment selling has been used in the sale of stocks and bonds, but apparently not with any great success.

Instalment selling in the United States is overwhelmingly in the form of conditional sales. Legal regulation of these sales varies from state to state; in a number of states the seller cannot retain title to goods sold on time and such conditional sales are not recognized as valid legally against third parties. There is agitation for the enactment of similar laws in other states. In the event the buyer defaults his payments the seller generally has three recourses: he may sue to recover the purchase price, he may foreclose the mortgage or he may repossess the commodity. Definite regulations are provided for in the Uniform Conditional Sale Act adopted in many states; the seller, for instance, may repossess but he must give the buyer at least twenty days' notice; if the buyer does not meet his obligations, the commodity is repossessed and sold at public auction. Efforts are being made to secure uniform laws governing instalment sales; meanwhile the National Association of Finance Companies is trying to standardize selling practises.

Instalment buying in England is known as "hire purchase" and has been in use for many years in various branches of the furniture trade. In this form of sale the owner agrees to rent the article to the hirer or lessee (in reality the purchaser) for a stated period and stipulates a certain number of instalments for rent; after the last one the lessee has the option of purchasing the article for a nominal sum, possibly no additional sum at all. The hire purchase system has made great strides since 1922, stimulated by overproduction in certain lines of trade and by the business slump. According to the Hire Traders' Protective Association instalment sales in 1927 accounted for 50 to 80 percent of the sales of automobiles; 70 percent of sewing machines, phonographs and pianos; 50 percent of furniture; and 10 percent of jewelry. Considerable

concentration prevails; a few large London firms with stores in various provincial towns do most of the business in instalment furniture.

French law recognizes a form of conditional sale, known as *vente à tempérament*, in which the title passes to the buyer. The seller cannot retain title to the article sold nor can he repossess it if the buyer defaults payment; the seller must sue in the courts. This legal restriction compels the instalment seller to be unusually careful in granting credit and eliminates much high pressure selling. Yet instalment selling is widespread in France; from 50 to 75 percent of motor cars are sold on time.

In Germany instalment selling under which title to the property remains vested with the vender has become increasingly popular in recent years. It almost disappeared during the inflation period but has since acquired a volume approaching in relative magnitude that of the United States. Approximately 75 percent of automobiles and furniture is sold on instalments. A considerable quantity of agricultural machinery is sold on time, one finance company devoting itself exclusively to that field. Banks participate directly in the capital and management of many instalment finance companies.

Instalment selling is found in almost all other countries; it has recently made considerable progress in the Balkans, Latin America and Japan. In all of these countries the articles sold on instalments consist mainly of furniture, automobiles, sewing machines, bicycles and musical instruments; they do not include, owing to different standards of living, some of the articles most commonly bought on instalments in the United States, such as electric washers, vacuum cleaners and electric refrigerators; nor are clothing and jewelry included to any large extent. Instalment selling in Europe and Latin America has been greatly stimulated by the sale of American automobiles abroad, a large proportion of which are sold on terms similar to those used in the United States. In Europe the proportion of automobiles sold on time payments averaged 61 percent in 1927-28, ranging from 15 percent in Spain to 80 percent in Denmark.

The recent expansion of instalment selling in the United States originated in developments in the automobile business. In the beginning of the industry manufacturers sold all cars at wholesale strictly for cash and urged retailers also to sell for cash. In time, however, through a desire to increase sales (emphasized by a great increase in plant capacity) the manufacturers changed their

attitude in regard to the granting of credit by the retailer to the consumer. The easy terms which were finally granted to the consumer increased sales and output; this coincided with an immense increase in productive efficiency, and the combination of these factors produced lower prices. These in turn increased sales and output, bringing about a still further expansion of plant and equipment. This expansion of plant capacity exceeded the capacity of available markets to absorb new cars, leading to an increase of both competition and instalment selling. Thus the automobile business developed the instalment system to a degree that made its former efforts seem comparatively insignificant. By 1923, however, the increase in automobile instalment sales slowed down considerably; and the finance companies sought new business in other fields, thereby becoming an important factor in the spread of instalment selling.

Other fields of business were prepared for instalment selling by poor sales and excess productive capacity during the depression of 1920-21. In the years just prior to 1920 plant and equipment had been expanded in the hope of great profits which were possible in the period of rapidly rising prices; and when the depression came some of these industries burdened with large overhead costs profited by the experience of the automobile industry and resorted to easy terms to the consumer as a means of increasing sales. The upsurge of prosperity in 1923 again increased plant capacity and competition; instalment selling spread. Following this period new products such as radios and electric refrigerators were seldom sold for cash; while instalment sales slackened in the case of automobiles and were stationary in the case of pianos they increased over 200 percent in the case of radios.

Competition among those selling the same kind of goods is a causal factor in the growth of instalment sales. If partial payment selling in a certain line of business stimulates sales and is otherwise successful, the manufacturer or retailer who refuses to use this device suffers. Under a regime of competitive business whatever is generally advantageous becomes a necessity for all competitors. Competition first forced the granting of instalment credit and then the offering of easier credit conditions in smaller down payments and a longer time in which to pay the balance. The tendency in some instances to depart from standard conservative terms may also be attributed to competition among retailers engaged in the same kind of business, among

manufacturers producing the same commodity and among finance companies and banks for business in lending funds to finance instalment sales.

Another factor in the spread of instalment selling is the competition between different kinds of goods, the type of competition which was intensified in the period from 1922 to 1929. It is believed generally that the public would purchase fewer radios, automobiles, mechanical refrigerators and the like if it were obliged to pay for them in a lump sum; and that consequently the purchasing power now expended on these commodities would, unless it were saved, be diverted to the purchase and consumption of other commodities. If the individual pledges his future income for automobiles, pianos and vacuum cleaners he will buy less clothing, food or the like than he would otherwise unless he is able to increase his income under the stimulus of instalment debts. In the opinion of many observers this latter condition is possible only in isolated cases and within narrow limits; consequently one of the effects of the increase in instalment selling has been a diversion of purchasing power from one group of goods to another. Instalment selling tends to slow down the sales of goods which cannot be sold on time payments; at the same time, however, it tends to induce consumers to purchase durable rather than ephemeral goods.

Modern methods of advertising and high pressure salesmanship produced by the intensification of competition have been partly responsible for the extension of instalment selling. Instalment goods are among the most heavily advertised, and this advertising is an important factor in the diversion of purchasing power facilitated by instalment selling. Advertising and instalment selling combine to determine wants by increasing the prestige and popularity of certain wants as against others.

When considered from the side of the demand for goods on instalment terms a very real factor in the instalment movement is to be found in the increase of the income of the wage earning and salaried groups. In recent years the middle class has increased in both numbers and income to a greater extent than any other section of the population; real wages have increased over 25 percent in comparison with pre-war wages and there has been a similar increase in the salaries of clerical employees. The larger part of these gains in income were secured during the period from 1920 to 1925, the very time in which instal-

ment buying assumed large proportions. The increased income meant that people could buy, pay for and consume more than formerly on any terms of sale and undoubtedly helped to stimulate the growth of instalment selling. Other forms of merchandising, however, such as mail order and cash and carry purchases, also greatly increased during the years of rapid growth of instalment selling. Credit facilities hitherto unavailable were offered to consumers through the development of finance companies, and the increased real income of the consumers gave them more than sufficient purchasing power to meet all their instalment obligations as they came due.

Before the recent expansion of the system buying on the instalment plan, except in the case of houses, was practised almost entirely by the poor and by the unstable groups in the community. Losses to the dealers were great, and consequently the price charged for the credit was so high that only those who could not possibly make other arrangements bought on instalments. Up until about fifteen years ago there was strong social disapproval of the practise and there is still a certain stigma attached to some types of instalment buying. It is only within the last ten years that the practise has become generally respectable.

At the present time instalment buying is not confined to the poorer classes. All economic groups except the very rich practise it extensively. Stores with a high class clientele sell furniture on instalments. Seven or eight years ago higher priced automobiles were sold on time payments only very quietly, but for the last few years they have been sold in the same manner and under the same conditions as cheaper cars. Electric refrigerators, too expensive to be bought by the poor, are sold largely on an instalment basis. While the largest number of instalment buyers is still to be found among the lower income groups, the total value of their purchases is probably less than that of the other groups; in fact, the great sources of instalment buying are probably among the middle class and upper layers of skilled workers. Nor is instalment selling confined to any particular section or sections of the country; it is well established everywhere, in both urban and rural districts.

One of the effects of instalment buying has been the creation of a new middleman, the finance company, the business of which has grown to great size within a few years' time. The selling of automobiles on the partial payment plan created a demand for some special agency to

finance the sales; the finance companies which were organized to supply this need made possible the growth of instalment buying by providing the necessary credit facilities for the extension of the system. Each new increase in instalment buying resulted in a still greater demand for the services of the finance companies, which rapidly increased in size and number. In function these companies are in certain respects like commercial banks, although very few of them are incorporated under the banking laws and subject to regular examination by the state banking departments. It is one of their functions to supply funds with which dealers can buy and carry a stock of goods. This activity is sometimes referred to as wholesale financing. They also extend credit on a large scale to individual purchasers of goods bought on the instalment plan. This is sometimes called retail financing. The one service helps the dealer to buy goods, the other helps him to sell them on the instalment plan. In the final analysis instalment financing is accomplished by borrowing from commercial banks; the major finance companies borrow to the extent of five times their capital resources, with a smaller ratio among the smaller companies.

The practises of finance companies in extending credit to individual purchasers of goods bought on the instalment plan are so varied that it is impossible to generalize as to their methods. In the case of the automobile business, however, considerable uniformity exists. When an individual buys an automobile on the instalment plan he is usually required to pay in cash one third of the purchase price and to give a note which provides for a schedule of equal monthly payments to be made over periods of time ranging from three to twelve or more months. The dealer if he is able to do so sells these notes outright to a finance company and thus receives cash for the goods sold on the instalment plan. When the dealer is able to sell the notes in this manner his legal responsibility ends. In most cases, however, he is required to endorse his customer's paper and assume the responsibility for its payment. Some of the finance companies discount the instalment notes in the regular way with banks located in the territory in which the notes originate. Others place their receivables in trust with some trust company and issue short term debentures against the trustee's notes, which are sold to banks. Sometimes collateral trust bonds running for a period of about ten years are sold. In any case the finance company

secures additional funds with which to finance more instalment sales.

Finance companies were at first organized by men not connected with the producing enterprises, but later automobile companies formed their own finance companies (for example, the General Motors Acceptance Corporation organized in 1919). Some important finance companies are subsidiaries of commercial banks; generally, even when affiliated with a particular industry, the companies do a diversified business. There has recently been a tendency for finance companies to combine; this has been influenced not only by problems peculiar to the financing field but by the general tendency of American business. Concentration and centralization of control are accompanied by localized management; some of the finance companies have subsidiaries in foreign countries. In June, 1930, four finance companies had instalment paper outstanding amounting to \$525,040,000, or approximately one quarter of the total. The business is profitable, losses are small and failures are few. One of the larger finance companies, the Commercial Credit Corporation of Baltimore, with assets of \$171,000,000 in 1930 paid over a period of nine years 85 percent in stock dividends in addition to substantial cash dividends. The General Motors Acceptance Corporation with a capital of \$50,000,000 and assets of \$381,000,000 has an excellent dividend record; it paid 8 percent in 1923, 1924 and 1925 and 12 percent from 1926 to 1931 in addition to extras of 3 percent in 1926, 5, 7, and 8 percent in 1927, 1928 and 1929 respectively and 16 percent in 1930.

The development of the finance company has had the economic effect of making possible more steady production in an industry where demand for the product is seasonal. The volume of sales of automobiles in the beginning of the industry was subject to extreme seasonal fluctuations; they became more moderate with the improvement of roads and the increased use of closed cars, but demand still varies considerably through the year. The industry has therefore been confronted with the difficult problem of how to secure steady production to meet a seasonal demand. The manufacturer's own capital as well as what he could borrow was needed for manufacturing purposes; this and other factors made it impossible for him to carry his entire output over the winter months. He did not have adequate storage space; even if he could have provided it, the problem would not have been solved, for cars must be distributed geographi-

cally before the spring demand arises. The dealer could not take the cars off the manufacturer's hands because he did not have funds of his own and could not secure them from the regular banks for this purpose. The development of the finance company solved the problem. It extended credit to the dealer permitting him to lay in his stock as it was finished at the factory. The manufacturer was paid in cash. Production was continuous. Transportation was more easily effected as it was spread over a longer time and the spring rush was lessened. The dealer was able to show his stock on his sales floor and have it ready for immediate delivery in order to meet the seasonal demand.

Finance companies and retailers are able to extend credit to individual instalment buyers because they in turn are able to borrow from banks. Some large retailers who have well organized credit departments carry on their instalment business without the service of finance companies and borrow directly from the banks to finance their instalment sales. Thus one of the costs to the finance company or the retailer is the interest that must be paid on borrowed funds. A second element of cost is that of a sum sufficient to cover losses in the case of individual buyers who default in payment. While complete statistical information is lacking, it is reported that the losses sustained by finance companies as a whole average 0.5 percent; in automobile paper the loss is small, as low as 0.2 percent on aggregate new and used car paper. It should be observed that the finance company's rate of loss does not show the loss sustained by the dealer. Some of the paper was "recourse" paper, that is, paper carrying the dealer's endorsement and for which the dealer stood the losses; in such cases the finance company lost nothing except in the event of the dealer's default. In reference to the losses sustained by dealers the statistics compiled by the United States Department of Commerce, based on a study of 10,992 representative retail establishments located in all sections of the country and representing all the principal lines of retail trade, show that the average bad debt loss on instalment sales in 1929 was 1.2 percent. These losses ranged from an average of 0.2 percent for those selling coal, wood, lumber and building material to an average of 7.9 percent for general clothing stores. A third cost is that of making the preliminary credit investigations which are necessary if the credit is extended wisely. A fourth expense is incurred in the provision of the necessary facilities for making col-

lections on many small notes from numerous customers. There are other costs, particularly those in the nature of overhead expenses, such as the maintenance of places of business and the salaries of officers and general managers.

The cost of instalment credit to the consumer as evidenced by the difference between the cash and credit prices of goods varies greatly, ranging from nothing (where the cash and credit prices are the same) to as much as 80 percent, depending upon the individual transaction. Extensive inquiry among retailers of all kinds as to the cash and credit prices of various commodities and examination of the rate schedules of a number of finance companies indicate that the usual cost of instalment credit ranges from 10 to 40 percent. Nominal interest rates are of course lower, but the real cost to the borrower becomes larger because of the fact that the debt is repaid in instalments. In many cases the dealer increases the cash price of articles so that the spread between the cash and instalment price shall not appear excessive.

Reasoning a priori individuals in both the United States and Europe have come to widely different conclusions in regard to the effect of instalment buying on saving. Business men have frequently advised their employees to go into debt for homes on the ground that it will give them a stake in the community and their job and will make them work harder and save more in order to meet their financial obligations. It is also set forth as a reasonable supposition that if the individual is not paying for furniture, vacuum cleaners and washing machines he is apt to spend his odd dollars in the theater or for other ephemeral luxuries. It is also a fact that if the life of the commodity purchased is longer than the period of payment a saving has taken place. If, for example, the automobile has been paid for before it is worn out, the purchaser has made a saving—provided he has not taken the money out of his savings account or mortgaged his house to complete the payments on the automobile. On the other hand, it is stated that instalment selling causes people to buy and consume luxuries which they would not buy if they were required to pay cash. It is argued that the instalment buyer soon acquires the luxury habit by being able to possess these articles, and that the luxury habit thus acquired leads to spending and consuming rather than to saving. Those who think that instalment buying is not conducive to saving mention frequently the demoralizing effect of too much debt on the individual. Against this view it

may be argued that instalment buying substitutes a plan or orderly method of payment for arrangements which sometimes have had little system in them, and consequently has a distinct disciplinary value.

Instalment buying in its present volume has existed for a comparatively few years, and experience with it has been too brief to prove anything conclusive in regard to its effect upon savings. The goods bought and paid for on the instalment plan between 1920 and 1929 were apparently not paid for out of savings; while large quantities of goods were being bought and paid for and perhaps only partly consumed, the savings of all income groups were apparently increasing at an unusual rate. The statistics on savings are not conclusive, but they do seem to indicate that savings are at least not declining because of instalment selling. It is true that the \$2,500,000,000 of outstanding instalment debt is a liability of the instalment buying group. But it is also true that this liability is perhaps more than covered by assets in the form of more or less durable goods. Finally, there is a growing belief that savings have been overstressed in the past and that spending is as important a factor as saving in promoting economic progress and stability. The danger is that the individual unprotected by a comprehensive system of social insurance may ignore the needs of illness and old age in his urge to spend.

When first introduced instalment sales create new consumer purchasing power. The instalment debt outstanding at any given moment represents goods which would not otherwise have been sold or produced. Since instalment selling is necessarily limited to particular kinds of goods, there are limits to its expansion. When that limit is reached and stabilization sets in, instalment selling becomes an ordinary institutional factor in the business mechanism and ceases to be an additional stimulus to increasing production. This may have a disturbing effect on an industry keyed up to unusually rapid expansion, an effect which becomes still more disturbing if instalment sales decline.

Instalment selling also exerts a decided influence on the character and structure of industry. Most of the goods sold on time are of the more durable variety; in 1928 the instalment sales of automobiles, radios, washing machines, mechanical refrigerators and similar goods accounted for approximately 70 percent of all instalment sales. Instalment selling therefore stimulates the expansion of mass production industries with high

fixed charges—industries which are characteristic of modern large scale production.

During the period of greatest growth in instalment selling, between 1920 and 1925, it was frequently predicted that the next period of business depression would destroy the instalment system if not the entire retail credit structure. It was pointed out that because of the widespread unemployment which would result consumers would not be able to meet their obligations; there would therefore be a flood of repossessions, enormous credit losses and frozen accounts receivable, all of which would subject the credit structure to unbearable strain. Instalment risks, however, are highly diversified, spread over many classes of people. In a depression only a part of the population becomes unemployed, and the portion of the population subject to the unemployment hazard includes only a fraction of those who have instalment payments to make. Moreover the instalment buyer usually strains all resources to make his payments and thus prevent repossession. It is not to be overlooked that a certain period of time elapses between the outset of the crisis and the point at which unemployment becomes really acute, an interval sufficiently long for a considerable proportion of the outstanding debts to be repaid. Finally, instalment buying is not confined to wage earners and salaried employees. The income of other groups of instalment buyers is not so seriously affected by the depression as to endanger repayment; while the purchasing power of the fixed income groups is in fact increased by the fall in prices.

This view is apparently confirmed by the experience of the depression year 1930. Statistics gathered by the retail credit survey of the United States Department of Commerce show that changes in 1930 in comparison with 1929 were not of a serious nature. True, repossessions, past due payments, losses and management expenses increased and the earnings of finance companies declined, although lower interest rates in borrowed money constituted a favorable factor for the companies. Numerous individual dealers and purchasers had trouble with their accounts; the strain on many instalment buyers, forced to restrict expenditures or borrow money to meet their payments, was severe. But considering the fact that 1929 was on the whole a year of unusual business activity the changes were small. There were no disturbing increases or decreases in credit sales in relation to cash sales. Current obligations in the form of instalment accounts

for the first fourteen months after the crisis were paid in an orderly manner and new goods bought on these terms in the same proportion to cash sales as formerly, both showing approximately the same relative decline. Taking the system as a whole, instalment credit stood the test of business recession in a manner that may be considered satisfactory.

While instalment payments are met and the system satisfactorily withstands depression, an undoubted decrease in immediate consumer purchasing power takes place. Persons whose incomes decline make their instalment payments, but they are paying for goods previously bought and to that extent are unable to buy new goods. This is offset by the creation of new purchasing power when instalment sales are increasing, but that is not true in periods of depression when instalment sales decline. They declined sharply in 1930-31, years of depression; in the first nine months of 1931, for example, instalment sales of automobiles declined \$472,000,000, a drop of 20.4 percent over 1930. Precisely as instalment selling tends to increase prosperity it tends also to deepen and prolong depression; when, however, instalment selling begins once more to increase and create new purchasing power it becomes a contributing factor in business recovery.

Instalment selling according to all indications is here to stay; it has assumed a definite place in the institutional arrangements of business enterprise. The system, however, will probably show no unusual expansion in the future as it did in the recent past; instalment selling will depend more closely on the general rate of economic progress or regression.

INSTINCT. The concept of instinct goes back, in a vague way at least, to Plato and Aristotle; it lacked specific definition among the Greeks because they did not distinguish clearly between inherited and acquired traits. With the revival of Greek philosophy in the Middle Ages the concept of instinct again appeared, especially in St. Thomas Aquinas, where it was identified more or less clearly with the idea of natural law working through the individual to produce responses that are inherent in his spiritual endowment. These spiritual endowments derived from natural law were fairly similar to the Aristotelian theological categories of the virtues and the vices. By the eighteenth century they had evolved into the definiteness of conscience, benevolence, sympathy and other moral sentiments and were basic to the philosophy of the English and Scotch ethicists of the seventeenth and eighteenth centuries, whose intellectual tradition harked back through Calvinistic predestination to natural law. The term instinct came into use with especial frequency in the writings of the eighteenth century and was made to refer not only to the

moral sentiments but also to the natural mental endowment. Specific instincts were rarely mentioned by name, and the concept remained for the most part general until well into the nineteenth century.

The growth of biological analysis in the middle of the nineteenth century and the rise of physiological psychology immediately thereafter as well as the great prestige of the biological approach to the study of man in that century stimulated the detailed analysis of mental heredity and the resultant classification of the instincts. This work was practically all speculative and *a priori* rather than experimental because of the difficulty of developing objective methods of analyzing the genetic aspects of behavior. The Germans, particularly Preyer, a disciple of Darwin, following the more general emphasis of the Scotch and English ethicists as well as the new biology, developed lists of specific instincts and attempted to apply these to the analysis of child and adult behavior. In the United States William James followed the newer German lead and developed some fifty separate instincts, but he in turn was surpassed in the matter of quantity by later psychologists, notably by Thorndike and Woodworth. In Great Britain the same tendency to particularize instincts developed a little later under the leadership of McDougall. The groups working in education and social psychology, which increased rapidly after 1900, took over the trend and developed a large variety of classifications.

As late as 1918 or even 1920 the active or passive support of the instinct hypothesis in the United States by psychologists, sociologists and educationists appeared to be almost unanimous; and the economists, political scientists and historians were beginning to develop an interest in the concept of instinct along with their expansion in the direction of a psychological orientation of their disciplines. As late as 1917 Dewey, for example, emphasized the importance of the instinct interpretation for social psychology. By 1922 he had shifted to a basic emphasis upon the importance of habit in character integration. Between 1921 and 1925 an acrimonious controversy arose over the question of instinct, and after the smoke and confusion were dissipated it seemed quite evident that the anti-instinctivists held the best positions on the field. The pro-instinctivists began to rearrange their broken legions in the form of redefinition and of substitute categories, such as drives, desires, wishes, *hormic* urges and prepotent reflexes;

others retreated and took up position with the endocrinologists, psychoanalysts, gestaltists and other diverse schools. In Great Britain the criticism of the instinct usage and hypothesis is only now beginning in earnest, while on the continent, where the instinctivist interpretation never became much of a scientific fad, the mild and relatively passive emphasis upon a general instinct interpretation continues.

Many conceptions of instinct have obtained since the term came into use. It can scarcely be said that there was any definite basis for a careful discrimination between inherited and acquired elements in so-called instinctive behavior until the critical work of Weismann and Mendel became generally available. The old metaphysical concept of natural law as the source of human behavior and character did not contain a theory of biological inheritance, although it leaned toward one in its later phases and thus favored the biological interpretation of instinct without eliminating entirely the environmentalist interpretation. The Lamarckian theory, which in the nineteenth century made the transition from the natural law to the scientific or analytic explanation of the origin and integration of human traits, combined in true eclectic fashion the concepts of environmental and hereditary factors without analyzing either concept in detail. The forced abandonment of the Lamarckian eclecticism brought about by the experimental work of Mendel, Weismann and others ultimately forced the analysis of the concept of instinct in purely biological terms. This analysis was finally performed by the present writer, thus forcing the issue of the controversy in terms of inherited biological structure and acquired or conditioned behavior patterns. It became evident that most of the so-called instincts were not inherited mechanisms but either acquired patterns of behavior or even conceptual language categories embracing large fields of functionally (not structurally) similar behavior. The new criticism on the basis of structural (including endocrine) biological analysis also forced the abandonment of the widespread practise of defining and classifying so-called instincts in terms of their adjustment functions instead of in terms of their genesis. More popular uses of the term instinct, making it equivalent to unconscious, unpremeditated, habitual or automatic activity, are being eliminated from writings in the field of the mental and social sciences, although they still freely persist among litterateurs and publicists, who usually come in contact with scientific criticism.

only indirectly and frequently a generation or more after it has been made.

The definition of instinct most widely accepted has been essentially biological and has varied but little, if at all, in its general conception since the middle of the last century, although it has been subjected to greater precision of detail as biological knowledge has itself become more precise. In its simplest precise form this definition of an instinct may be stated as a specific and definite inherited or unlearned response which follows or accompanies a specific and definite sensory stimulus or organic condition that serves as a release to the inherited mechanism. This definition of instinct bars both the conception of acquired instincts and the related conception, not infrequent in German and continental philosophic literature, that instincts are inherited behavior patterns which were at one period of the history of the race the result of rational adaptation.

Among the most significant results for the social sciences of this stabilization of the instinct concept has been the revised outlook upon human society and social control made possible to the social scientist, the educator, the legislator and the administrator. The social scientists are confronted with the problem of distinguishing inherited forms of behavior from those which are acquired. The narrowing of the scope of inherited behavior patterns as thus analyzed must frequently turn the educator, legislator and administrator, in the face of some difficult personality or social situation, from the barren statement that "You can't argue with an instinct" or "You can't change human nature" to an intelligently constructive social program which will remove the obstructing or perverting conditioning factors and stimuli and lead them to substitute new environing pressures more favorable to the production of the desired adjustment. The effect of the more critical study of instinct upon the subject matter and orientation of the social sciences themselves has been even more marked. The most immediate and thoroughgoing response to this analysis was from sociology and the branch of social psychology which works from the standpoint of sociology; these disciplines were somewhat distantly and haltingly followed by social work, which is considerably under the influence of the psychoanalytic theories regarding instinct. The uncritical use of the term instinct by a branch of the institutional school of economics under the leadership of Veblen, who misapplied the erroneous

concept in an otherwise brilliant analysis of society, has been turned into a more fruitful environmental and cultural analysis of traditional and conventional factors conditioning economic behavior. Political psychology, which at first responded to an instinct interpretation under the leadership of Graham Wallas, is now recovering its balance through environmental and personality analysis. Psychology, which has closely trailed biology during recent decades, was slowest to respond generally to the new critical findings regarding instinct; but very recently the biologists themselves have begun not only tacitly but also openly to accept the environmental analysis and interpretation of the factors which are responsible for the cultural elements in human behavior.

INSTITUTION is a verbal symbol which for want of a better describes a cluster of social usages. It connotes a way of thought or action of some prevalence and permanence, which is embedded in the habits of a group or the customs of a people. In ordinary speech it is another word for procedure, convention or arrangement; in the language of books it is the singular of which the mores or the folkways are the plural. Institutions fix the confines of and impose form upon the activities of human beings. The world of use and wont, to which imperfectly we accommodate our lives, is a tangled and unbroken web of institutions.

The range of institutions is as wide as the interests of mankind. Any simple thing we observe—a coin, a time table, a canceled check, a baseball score, a phonograph record—has little significance in itself; the meaning it imparts comes from the ideas, values and habits established about it. Any informal body of usage—the common law, athletics, the higher learning, literary criticism, the moral code—is an institution in that it lends sanctions, imposes tabus and lords it over some human concern. Any formal organization—the government, the church, the university, the corporation, the trade union—imposes commands, assesses penalties and exercises authority over its members. Arrangements as diverse as the money economy, classical education, the chain store, fundamentalism and democracy are institutions. They may be rigid or flexible in their structures, exacting or lenient in their demands; but alike they constitute standards of conformity from which an individual may depart only at his peril. About every urge of mankind an institution grows up; the expression of every taste and capacity is crowded into an institutional mold.

Our culture is a synthesis—or at least an aggregation—of institutions, each of which has its own domain and its distinctive office. The function of each is to set a pattern of behavior and to fix a zone of tolerance for an activity or a complement of activities. Etiquette decrees the rituals which must be observed in all polite intercourse. Education provides the civilizing exposures through which the potential capacities of individuals are developed into the abilities for performance, appreciation and enjoyment which are personality. Marriage gives propriety to the sex union, bestows regularity upon procreation, establishes the structure of the family and effects such a mediation as may be between personal ambition and social stability. A number of

institutions may combine and compete to impress character upon and give direction to the mass of human endeavor. The state claims primary obedience and imposes a crude order upon the doings of mankind; the law by punishing offenses and settling disputes determines the outermost limits of acceptable actions; morality with neater distinctions and more meticulous standards distinguishes respectable from unconventional conduct. The community is made up of such overlapping provinces of social government. It is the institution in its role of organizer which makes of this a social and not a monadic world.

It is impossible to discover for such an organic complex of usages as an institution a legitimate origin. Its nucleus may lie in an accidental, an arbitrary or a conscious action. A man—savage or civilized—strikes a spark from flint, upturns the sod, makes an image of mud, brews a concoction, mumbles a rigmarole, decides a quarrel or helps himself to what he may require. The act is repeated, then multiplied; ideas, formulae, sanctions and habits from the impinging culture get attached; and gradually there develops a ritual of fire, a hoe and spade agronomy, a ceremonial for appeasing the gods, a cult of healing, a spell for casting out devils, a due process of law or a sound business policy. Even if it is deliberately established an institution has neither a definite beginning nor an uncompromised identity. A religious creed or a legislative statute is compounded of beliefs and ideas which bear the mark of age and of wear; a paper charter and a document engrossed upon parchment are not insulated against the novelties in usage which attend the going corporation and the living constitution. It is impossible even in the most rudimentary culture to find folkways which are simple and direct answers to social necessities. In all societies, however forward or backward, the roots of the most elementary of arrangements—barter, burial, worship, the dietary, the work life, the sex union—run far back into the unknown past and embody the knowledge and ignorance, the hopes and fears, of a people.

In fact as an aspect of a continuous social process an institution has no origin apart from its development. It emerges from the impact of novel circumstances upon ancient custom; it is transformed into a different group of usages by cultural change. In institutional growth the usual may give way to the unusual so gradually as to be almost unnoticed. At any moment the familiar seems the obvious; the unfamiliar appears but a little revealed—an implication in a

convention which is itself taken for granted, a potentiality slowly quickening into life. So it is that the corporation is still a person, the work of the machine is manufacture, the labor contract concerns masters and servants and industrial accidents are personal wrongs. It often happens that new arrangements spring up under the cloak of an established organization. Thus the empire of the Caesars emerged behind the forms of the republic, the holy Catholic church is nominally the episcopal see of Rome and the British Commonwealth does its business in the name of His Majesty. In like manner in the domain of ideas the novelty in doctrine usually appears as a gloss upon the ancient text; systems of theology are commentaries upon the words of Scripture; Coke and Cooley set down their own understanding of the law upon the authority of Littleton and Blackstone. Thus too so intangible a thing as a social theory or a public policy may emerge from the practical commitments of the moment. A mere expediency, such as the abolition of the corn laws, is abstracted from cause and occasion and becomes a generalized policy of free trade; or a comprehensive scheme of railway regulation, such as obtains in the United States, appears as a by-product of the empirical elimination of specific abuses. In the course of events the fact arrives before the word and new wine must be put up in old bottles. Novelty wins a tacit acceptance before their strangeness is noticed and compel before their actuality is appreciated. In institutional life current realities are usually to be found behind ancient forms.

As an institution develops within a culture it responds to changes in prevailing sense and reason. A history of the interpretation of Aristotle or St. Paul or Kant at various periods indicates how easily a document lends itself to successive systems of ideas. The public regulation of business has consistently even if belatedly reflected the prevailing winds of doctrine upon the relation of the state to industry. The pages of the law reports reveal the ingenuity with which, in spite of professions that the law remains the same, old rules and standards are remade to serve changing notions of social necessity. An institution which has enjoyed long life has managed to make itself at home in many systems of thought. The classic example is the Christian Gospel. The simple story of the man Jesus presently became a body of Pauline philosophy; the Middle Ages converted it into an intricate theological system and the rationalization of a powerful ecclesiastical empire; at the individualistic

touch of the Reformation it became a doctrine of the personal relationship between man and his maker; it is today patching up a truce with Darwinism, the scientific attitude, relativity and even religious skepticism. In this continuous process of the adaptation of usage and arrangement to intellectual environment an active role is assumed by that body of ideas taken for granted which is called common sense. Because it determines the climate of opinion within which all others must live it is the dominant institution in a society.

In an even broader way an institution is accommodated to the folkways of a culture. As circumstances impel and changing ideas permit, a usage in high esteem, like piracy, may fall from grace; while another under tabu, such as birth control, may first win tolerance and in time general acceptance. As one social system passes into another and the manner of living and the values of life are transformed, one institution gives way to another better adapted to the times. It required a number of changes in use and wont to convert the ordeal by combat into the trial by law; the prestige of the family tie, of blood vengeance, of the magical ritual and of might made right had to decline and a consciousness of the waste and injustice which attended legalized conflict had to become prevalent. An institution that survives, such as matrimony, responds surely even if stubbornly to cultural change. While the oasis of Christian marriage is no more than the primitive custom of monogamy, the rigid lines of the institution bear the marks of the mediaeval order. It gave support to a caste system resting upon landed property, elevated the social values of family above the individual values of love, was blessed with the ascetic ideal of otherworldliness and became a sacrament. Companionate marriage is emerging from a different world of fact, appreciation, habit and belief. It reduces to usage an attempt to escape the rigors of matrimony without resort to casual relationships; it reflects the condition of an urban society where blood is no longer blue, life is impersonal, children are a luxury and women must earn their own livings. In a culture which develops slowly enough to allow a graceful accommodation folkways may be drawn together into rich and intricate institutional patterns. In the Middle Ages the usages of the church—the trinity, the creed, the litany, the ecclesiastical empire—were all fused into a single conventional whole, to which unity was given by the idea of the death of the god as a vicarious atonement. In

the late eighteenth century politics, law, economics, ethics and theology in separate domains alike attempted to superimpose a symmetrical system of mechanical principles upon the mass of human behavior; the common element was an analogue borrowed from physical science. In the social process the life of an institution depends upon its capacity for adaptation. But always amid the whirl of change elements of disorder are present; and long before a harmony is achieved between unlike conventions disintegration has set in.

Nor is an institution introduced from an alien society immune to this process of development. The act of borrowing merely gives the opportunity for its transformation. The nucleus is liberated from its cultural matrix and takes on the character of the usages among which it is set down. In their native habitat the books of the Old Testament were the literature of a people; in the strange world of the mediaeval schoolmen they became a collection of verses inviting dialectical exposition. In England "the higher law" was invoked to justify a popular revolution against an irresponsible monarchy; in America it has become the sanction for a judicial review of legislative acts. In appropriating the machine process Russia stripped away the enveloping business arrangements and made of it an instrument to serve a national social economy. The act of transplantation may at first retard but eventually is likely to promote growth. It introduces into a culture an unknown usage but allows it to emerge as an indigenous institution.

Its very flexibility makes an institution a creature of social stress and strain. In a stable or slowly changing society it fits rather neatly into the cultural pattern; amid the disorder which change brings its office may be compromised by the inflexibility of its structure. As necessity changes, tradition and inertia may stand in the way of the performance of new duties. A group of usages, for all the new demands upon it, may never quite escape slavery to its past. The shadow of ordeal by combat still hangs heavy over trial by law; the jury decides the contest, the judge is the umpire, the procedures are the rules of the game, the witnesses are clansmen armed with oaths and the attorneys are the champions; an appeal court orders a new trial not primarily for want of justice but because of error in the conduct of the ordeal. The United States Supreme Court has come to be the official interpreter of the constitution; yet by tradition its function is judicial, and it is only as an issue is germane to

the disposition of a case that it can declare the meaning of the higher law. Almost every institution—from the superfluous buttons on the sleeve of a coat to the ceremonial electors in a presidential contest—bears the vestigial mark of a usage which is gone.

But its elements of stability may be powerless to prevent the conversion of an institution to a service for which it was never intended. Its existence and repute give it value; it may adventitiously or by design assume a new character and play a new role in the social order. Equity, once an informal method of doing justice, now possesses all the appurtenances of a system of law. The principle of "no liability without fault" was once the basis of an individualistic law of torts; in our times the rules of recovery are being socialized, as, for example, in workmen's compensation, by a mere extension of "fault" to acts involving no personal blame. An institution may even fall into the hands of the enemy and be used to defeat its reputed purpose. Thus a community of ascetics develops into a wealthy monastic establishment; a theory of social contract invented as a justification of monarchy is converted into a sanction for its overthrow; a party dedicated to personal freedom becomes the champion of vested wealth; and a philosophy contrived to liberate thought remains to enslave it. As time and chance present their problems, men meet them with expediences as best they can; but those who contrive rules and formulae cannot control the uses to which they are put. The proneness of an institution, like a lost sheep, to go astray, has been caught in the sentence: "Saint Francis of Assisi set out to bring people to sweetness and light, and left in his wake a plague of gray friars." The folkways are marked by a disposition of event to belie intent.

In the course of time the function of an institution may be compromised by or perhaps even be lost in its establishment. The spirit may become the letter, and the vision may be lost in a ritual of conformity. In time a way of intellectual inquiry may become a mere keeping of the faith; a nice propriety in social relations may decay into a code of etiquette; or a morality intended to point the way toward the good life may come to impose the duty of doing right. Thus ceremonial replaces purposive action and claims a vicarious obedience. The existence of an informal institution gets buttressed about by prevailing opinion and by personal interest. In legislative "deliberation" statesmen cherish their stock in trade of time honored argument and resent the

appearance of unfamiliar issues; scholars of repute defend the established ways of inquiry and the accepted verities; and social lights conserving the older proprieties against feminism "entrench themselves behind their tea-cups and defend their frontiers to the last calling-card." The persons immediately concerned have their stakes in arrangements as they are and do not wish to have personal position, comfort of mind or social prestige disturbed. As it crystallizes into reputable usages an institution creates in its defense vested interest, vested habit and vested ideas and claims allegiance in its own right.

If an institution becomes formal, an even greater hazard to its integrity is to be found in its organization and its personnel. A need for order finds expression in a government or the demand for justice in a legal system or the desire for worship in a church; and various groups become interested in its structure and offices, its procedures and emoluments, its ceremonials and consolations. A host of officials great and small comes into being, who are as solicitous about the maintenance of the establishment to which they are committed. They possess preferences and prejudices, are not immune to considerations of prestige and place and are able to rationalize their own interests. As the scheme of arrangements grows rigid, "the good of the nation"—or the church or the party or the lodge or whatever it is—tends to become dominant. The lines of activity may be frozen into rigidity and ecclesiasticism, legalism, constitutionalism and ritualism remain as fetishes to be served. An institution when once accepted represents the answer to a social problem. In the maze of advantage, accommodation, sense and reason which grows up about it lies a barrier to the consideration of alternatives. Its successor for better or for worse is likely to prevail only through revolution or by stealth.

In its ideal likeness an institution usually creates its apology. As long as it remains vital, men accommodate their actions to its detailed arrangements with little bother about its inherent nature or cosmic purpose. As it begins to give way or is seriously challenged, compelling arguments for its existence are set forth. The picture-as-it-is-painted is likely to be rather a work of art than a representation of fact, a product rather of rationalization than of reason; and, however adventitious its growth, disorderly its structure or confused its function, the lines of its defense lack nothing of trimness and purpose. The feudal regime was an empirical sort of an

affair; men of iron lorded it over underlings as they could, yielded to their betters as they were compelled and maintained such law and order as the times allowed; but with its passing its sprawling arrangements and befuddled functions were turned into office and estate ordained of God. In the days of the Tudors kings were kings without any dialectical to-do about it; the overneat statement of the theory of divine right had to await the decadent monarchy of the Stuarts. The tangled thing called capitalism was never created by design or cut to a blue print; but now that it is here, contemporary schoolmen have intellectualized it into a purposive and self-regulating instrument of general welfare. If it is to be replaced by a "functional society," the new order will emerge blunderingly enough; but acquisition of a clean cut structure and clearly defined purpose will have to wait upon its rationalizers. An assumption of uniformity underlies all apologies; invariably they impose simple, abstract names, such as monarchy, democracy, competition and socialism, upon a mass of divergent arrangements.

In this endowment with neatness and purpose an institution is fitted out with the sanctions and trappings of ancient usage. Republican government harks back to Greece and Rome; the "liberties" for which seventeenth century Englishmen fought were the ancient rights of man. Magna Carta, a feudal document, was remade to serve the cause of Parliament against king; a primitive folk government was discovered in the dim twilight of the German forests to give to English democracy a fountainhead which was neither French nor American; and "the spirit of '76" grew up long after the event to serve the patriotism of another century. In the courts it is a poor rule which cannot find a good reason in former decisions and fit itself out with an ancient lineage. But law does not invoke the sanction of precedent more often than other institutions; the openness of its written records merely makes more evident the essential process. A succession of usages stretching from Aristotle to Calhoun has been justified as expressions of the natural order. Even—or above all—in the church the prevailing dogma is set down as interpretations of the creed of the apostles; and Christian marriage "was instituted by God in the time of man's innocence." As tradition leaves its impress upon fact, fact helps to remake tradition. The thing that is is the thing that always was.

It is only as stability gives way to change that the lines of an institution stand out in sharp re-

lief. So long as a people is able to do as its fathers did it manifests little curiosity about the arrangements under which it lives and works; the folk of the South Sea Islands can administer justice after their ways, but they can neither give answers to hypothetical cases nor tell in abstract terms what they do. So long as the procedure of a group or a school is unquestioned it is little aware of the conventions and values which give character even to outstanding achievement: Scott had little conscious appreciation of the distinctive qualities of the English novel; Jowett could never have put in terms the peculiar features of Oxford education; and Kant might not have been able to place his own philosophy in time and opinion. But the break of usage from usage within a culture and the resulting maladjustment lead to a discovery of the detail which makes up an institution. A number of crises were required to reveal the customs which are the British constitution; it took a Civil War to make clear the nature of the union between the American states. The appearance of social unrest was essential to an appreciation of the difference between competition and *laissez faire* and between industry and business. An aesthetic revolt marked by a riding into almost all the winds that blow was requisite to a realization of the distinctive modes and values in classical music and in Gothic architecture and to an appreciation of the molds imposed by acceptable form upon creative effort. For such casual glimpses of the intricacies of social institutions as men are permitted to see they are indebted to the stress and strain of transition.

It follows almost of course that institutional development drives a fault line between current fact and prevailing opinion. Men see with their ideas as well as with their eyes and crowd the novel life about them into outmoded concepts. They meet events with the wisdom they already possess, and that wisdom belongs to the past and is a product of a by-gone experience. As new institutions gradually emerge from the old, men persist in dealing with the unfamiliar as if it were the familiar. A national legislature by the enactment of antitrust laws tries to superimpose the competitive pattern upon the turbulent forces of a rising industrialism; a trade union uses the traditional device of a strike to advance wages in an industry in which the unorganized plants can easily supply the total output; a group of elder statesmen approaches the problems of war debts and reparations with the old formula of protection versus free trade. At a time when a

depression bears witness to economic disorder the institution of business is discussed in the outgrown vocabulary of private property, liberty of contract, equality of opportunity and free enterprise; and rugged American individualism is invoked as a way of order for a system which has somehow become an uncontrolled and unacknowledged collectivism. Even the Protestants as often as not turn belief into denial; and heresy shackled to an inherited ideology is merely a reverse orthodoxy. In the flux of modern life the various usages which with their conflicting values converge upon the individual create difficult problems that demand judgment; and in the course of very human events it is the fate alike of individual, group and society to have to meet emerging fact with obsolescing idea.

Thus an institution like the living thing it is has a tangled identity. It cannot be shown in perspective or revealed in detail by the logical method of inclusion and exclusion. It holds within its actuality the vestiges of design and accident, the stuff of idea and custom, from many ages, societies, civilizations and climates of opinion. In any important group of institutions, such as marriage, property, the market or the law, there are to be discovered as inseparable aspects of an organic whole notions, procedures, sanctions and values hailing from cultural points far apart. Each holds within its being elements in idea and in form drawn from the contemporary era of relativity, the rational universe of the eighteenth century, the mediaeval world of absolutes and verities and the folkways of some dim far off era. An institution is an aspect of all that it has met, a potential part of all that it will encounter. It holds many unknown possibilities which a suitable occasion may kindle into life. It may continue to hold sanctions which we think have departed; it may already have come to possess compulsions of which we are still unmindful. The discovery of its meaning demands an inquiry into its life history; but even the genetic method will tell much less than we should like to know of how a thing which cannot for long abide came to be.

Moreover the way of knowledge is itself an institution. The physical world, natural resources and human nature may be elementary things; but we can learn about them only in terms of and to the extent allowed by our prevailing methods of inquiry. The little we understand of the universe is a function of the size of the telescope, the sensitiveness of the photographic plate and the bundle of intellectual

usages called astronomy. Our national resources are a product of technology, and their catalogues at different times reflect the contemporary states of the industrial arts. It was the steam engine and the machine which made of coal and iron potential wealth; it was not until Faraday and Edison had done their work that electricity became potential energy. The little we understand or think we understand about human nature is an institutional product. The inquiries called physiology, anatomy and neurology—each of them a bundle of intellectual usages—reveal no more than the raw material of personal character; the stuff has ripened into individuality within the matrix of the prevailing folkways. Man and woman are so much creatures of custom and belief that the word innate is most treacherously applied to masculine and feminine traits. In various societies the stages upon which peoples must play their parts are set so differently by social heritage that we can as yet speak with little certainty about racial characteristics. The physical world and the human nature we know are aspects of the prevailing state of culture. In matter and in the chromosome may lie limitless possibilities; the actualities which appear are creatures of social institutions.

Among the ways of knowing is "the institutional approach." Institutes as the ordained principles of a realm of learning or of life have long existed; they are known to theology, law, education and all subjects ruled over by dialectic. About the turn of the last century a genetic study of the folkways began to win academic respectability. It could make little headway so long as the Newtonian concept was dominant; inquirers went in search of laws and uniformities, explanations were set down in mechanical formulae and the end of the quest was an articulate and symmetrical body of truths. The institutional method had to wait until the idea of development was incorporated into academic thought and the mind of the inquirer became resigned to the inconsistency which attends growth. The analogy with a biological organism had to be renounced and a basis in ideology had to be discovered before it could become a fruitful method of study in economics, history, philosophy, law and politics. The practical impulse toward its use came with a change in public opinion; so long as laissez faire dominated our minds, dialectic served well enough to turn out explanatory apologies for the existing social arrangements; when we began to demand that order and direction be imposed upon an unruly

society, a genetic study of how its constituent usages had grown up into an empirical organization seemed proper. An inquiry into institutions may supply the analytical knowledge essential to a program of social control or it may do no more than set adventures for idleness. In either event the study of institutions rests itself upon an institution.

Accordingly an institution is an imperfect agent of order and of purpose in a developing culture. Intent and chance alike share in its creation; it imposes its pattern of conduct upon the activities of men and its compulsion upon the course of unanticipated events. Its identity through the impact of idea upon circumstance and the rebound of circumstance upon idea is forever being remade. It performs in the social economy a none too clearly defined office—a performance compromised by the maintenance of its own existence, by the interests of its personnel, by the diversion to alien purpose which the adventitious march of time brings. It may like any creation of man be taken into bondage by the power it was designed to control. It is a folkway, always new yet ever old, directive and responsive, a spur to and a check upon change, a creature of means and a master of ends. It is in social organization an instrument, a challenge and a hazard; in its wake come order and disorder, fulfilment, aimlessness and frustration. The arrangements of community life alike set the stage for and take up the shock of what man does and what he leaves undone. Institutions and human actions, complements and antitheses, are forever remaking each other in the endless drama of the social process.

INSTITUTIONS, PUBLIC. Public institutions care for individuals who are in need of aid or treatment and whose disadvantages of condition or personality have been accepted as a public responsibility. For the destitute, the mentally disturbed or incapable, the physically handicapped, the aged, delinquent and dependent children, persons accused or found guilty of crime, institutional care may seem desirable or necessary.

Institutional care for all these groups, except prisoners, owes its rise almost wholly to the Christian church. Although it is true that the literature of early peoples, notably the Hebrews, contains frequent admonitions relative to the care of the poor and needy, such provision was purely an individual responsibility devolving upon the family and friends of the afflicted. In the case of the Greeks and Romans provision by the state for its destitute took the form of the distribution of public largess. Particularly in time of famine corn, oil and other commodities were given out to the poor, a practise which was the precursor of modern "outdoor" relief.

Nowhere in antiquity, however, is there evidence of the establishment of large scale institutions for the sick and the destitute, a development which characterized the Christian church from its inception. Xenodochia, or houses of refuge for the accommodation of pilgrims, grew up under religious auspices in the East and in Italy, and they were followed soon afterward by hospitals. The latter, ministering to the aged, the widowed and orphaned as well as to the sick and disabled, gave rise to the almshouse, the most familiar mediaeval institution of charity. To the church likewise belongs the credit for the first orphan and foundling homes, hospitals for lepers and incurables and asylums for the insane. In addition to the various ecclesiastical organizations there were institutions developed by the merchant and craft guilds for the relief of distress among their own members.

Out of this religious and secular beneficence grew municipal and state care of the poor and destitute. Partly because of abuses by the monasteries and ecclesiastical organizations in the exercise of their charitable prerogatives and partly because of a desire to share in the revenues devoted to philanthropic activities the various states in Europe manifested an increasing desire during the late Middle Ages to gain control of hospitals and almshouses. By the time of the Reformation the groundwork of public welfare in Europe had been recast, the towns and cities

having assumed what had always been the function of church and guild.

The notion of government responsibility for the problems of poverty, dependence and delinquency has gained especially wide acceptance in the Scandinavian nations, where public welfare has been the business of the state from the very first and where private institutional charity is almost non-existent. In Germany after the Reformation the parish became a civil unit for the purpose of administering relief. At the present time institutional care is extensive and diverse and remains under the administration of the government, except for certain ecclesiastical institutions, which are, however, subject to state supervision. In France the trend from private or ecclesiastical to public control of welfare institutions gained momentum with the advent of the revolution when the National Assembly declared all hospitals and almshouses public property and took over their administration. The central commission of *bienfaisance* created by these administrators, although it was but meagerly effective during most of the nineteenth century, was a work destined to last and it furnishes the impetus for the present system of institutional as well as outdoor relief in Paris. In all these countries as a rule public institutions for charity or correction—institutions for the criminal, insane and pauper—are under the direction of a central bureau or governing board.

In Soviet Russia relief is based on the principle of state responsibility and of the right of all workers to receive assistance from the state during illness, infirmity, unemployment, old age or any other form of distress. Under the auspices of the People's Commissariat of Social Relief and the Institute for the Protection of Women and Children, sanatoria for the mentally and physically handicapped, homes for deserted children and orphans, crèches, maternity homes and hostels for unmarried or destitute mothers and numerous other public institutions have been established. Public health occupies a central place in the government welfare program and all hospitals, clinics and sanatoria have been nationalized. These institutions, together with the health resorts, spas, rest and vacation homes maintained for the benefit of workers, are administered by the People's Commissariat of Public Health. The state, however, places primary emphasis on pensions and insurance and on the various rehabilitation schemes whereby those in need of care are not only provided with temporary institutional relief

but are given treatment and education through which they are enabled to resume their normal status in society. This prophylactic effort is especially apparent in the case of criminals and delinquents who, even though they are confined in prisons or houses of correction, are given every encouragement to mitigate their stay and to reestablish themselves as citizens.

In England as on the continent in the early days relief of the poor and dependent was in charge of ecclesiastical authorities. With the dissolution of the monasteries by Henry VIII, however, it became necessary for the state to assume the responsibility. Efforts to cope with the alarming increase of mendicancy during this period culminated in the Poor Law of 1601, which with its later modifications and revisions forms the basis for most public welfare work today in the United States as well as in England.

Provision of institutional care for public charges in the United States was at first an entirely local function. It was performed through the almshouse, which was established on the same principles as the English workhouse. Like its English prototype, the almshouse was used for all varieties of public charges, except criminals, without regard to sex, age, health or habit. It harbored paupers and vagabonds, dependent children and epileptics, the insane, blind, deaf, crippled, diseased and aged. It was a town or county institution, almost everywhere mismanaged or neglected. Provision for the detention and custody of persons accused or found guilty of crime was also local and characterized by the weaknesses of local administration. Early in the nineteenth century, however, as the evils of the almshouse system came to be recognized, special groups began to be segregated and cared for in special state institutions. The sick poor, the insane, orphan or deserted children, persons charged with crime or already found guilty, came increasingly to be considered as state charges and as groups with special and varied needs.

The first state hospital for the insane was that authorized by the Virginia legislature in 1769 and opened in 1773. The principle of state care for insane persons whatever their pecuniary status has now been adopted in all the states. In 1798 Kentucky included in a statute containing many of the reforms in the criminal law urged for thirty years by the great English law reformers the provision for a state prison, to which persons convicted of felonious offenses anywhere in the state should be sentenced. Today every state has its prison. Early in the nineteenth cen-

tury private benevolence provided institutions for the education of the deaf in Hartford, Connecticut (1817), and in Danville, Kentucky (1824); and their national significance was held to be so great that Congress voted them grants of public land to be sold for funds. In the late 1820's and early 1830's Samuel Gridley Howe, the philanthropist and educator, led the way toward provision for the education of the blind in Massachusetts and later of the mentally subnormal. His undertakings, like those at Hartford and at Danville, were cooperative and public funds were paid to private organizations for definite services. State institutions for the education of deaf and blind children were soon opened elsewhere and today they are found in nearly every state. In the west, however, most of them have been public from the first.

It is still a question whether for certain types of needy the treatment should be given by the local unit or by the state. In Massachusetts state as distinguished from local responsibility was early recognized in the care of the "unsettled poor," and three state almshouses were opened in 1854. Also for the group of juvenile offenders, or delinquent children as they would be characterized today, Massachusetts, departing from the program of the prison reform group in England, established state institutions, one for boys in 1847 and one for girls in 1854. In nearly all states, however, the care of the destitute and the detention of petty offenders have continued in the hands of local authorities; and the almshouse and jail remain today as unsolved problems and sources of humiliation to local public welfare administrations.

The administrative organization of state institutions has shown a certain degree of uniformity but also within limits a great diversity. For the institutions caring for the mentally and physically handicapped, insane, feeble-minded, deaf, blind or delinquent the pattern in the beginning was generally a separate unsalaried board of trustees or directors, appointed by the governor or by the governor and senate for overlapping terms; the board was thus supposed never to be entirely renewed at once and was supposed to be assured continuity of policy and freedom from partisan interference. The members were expected to represent the interests of the entire state. Often the board was given the power to appoint the superintendent and the staff of the institution, but sometimes, as in the case of the Massachusetts state almshouses, this power together with that of appointing the board itself was vested in

the governor. Although in recent years the value of these boards has been widely questioned, no adequate basis of judgment as to their serviceability has been supplied. The problem is so complicated, the records kept are so diverse and so lacking in comparability that contradictory conclusions are urged by equally able and well meaning students of the public service.

The existence of a number of state institutions, which operated independently of each other, and of various local authorities, which often overlapped in function, caused inevitably a good deal of confusion. In Massachusetts, for example, in addition to the local institutions for the relief of the destitute and the local law enforcing agencies there were by 1860 nine state institutions, each, as reported by a special joint committee of the house and senate in 1859, "created without especial reference to others, and in no degree as a part of a uniform system," and four others that received grants from the legislature. Because of the varieties and anomalies in organization and the rapid increase in public expenditures for state charities, which in Massachusetts had almost quadrupled in twenty years and more than doubled in ten years, the establishment of a central state board of charities was recommended, to which should be given power of visitation, inspection, transfer of patients and general supervision; by the exercise of this power it was hoped that some unity, uniformity and economy might result. As a result of this recommendation Massachusetts created the Board of State Charities in 1863, thus marking the first state attempt at central supervision. Similar authorities were established in 1867 by Ohio and New York; in 1869 by Illinois, North Carolina, Pennsylvania and Rhode Island; in 1871 by Wisconsin and Michigan; and in 1873 by Kansas and Connecticut.

From that time the administration of public institutions has been inextricably bound up with the problem of the organization of centralized state welfare authorities. These authorities in the early years were with few exceptions supervisory boards, which were generally composed of unsalaried members appointed for overlapping terms, as in the case of the local boards of trustees. They were given wide powers of visitation and inspection and were called upon to make researches into the causes of pauperism and crime and to take action leading to greater uniformity of practise as well as to the possible adoption of preventive measures and programs; but they usually had no direct control in administration, the separate boards of trustees re-

taining the actual management. In some states, however, the boards of trustees were soon rejected. Wisconsin, for example, after a period of "supervision" of state institutions by a state Board of Charities and Reform, abolished the separate boards of trustees in 1881 and transferred the administration of those institutions to a state administrative board, a plan that was later widely followed in other states. In general the administrative boards are composed of salaried members with direct control over the management of state institutions. In 1909-11 a careful study was made of the administration of state institutions in New York, where there was "partial centralization" under three different commissions of supervision and control. For purposes of comparison the investigator studied also the systems in Indiana, where the state central authority merely supervised the boards of trustees, and in Iowa, where there had been from the time the central authority was set up the greatest possible measure of central administration. The results seemed to indicate that an institution of four hundred or over could be served under the Indiana system at least as well as and possibly better than under the Iowa system. The report recommended state supervision and partial control and an organization which included institutional management by the separate boards of trustees (Wright, H. C., *Report of an Investigation of the Methods of Fiscal Control of State Institutions in New York*, New York 1911).

In 1917 there was undertaken in Illinois a system of one-man supervision and control which has had great influence. The entire administration of the state was reorganized and its functions were divided among nine (later eleven) departments at the head of each of which there was a director appointed by the governor. Most of the duties and responsibilities connected with the administration of the whole system of charitable, penal and reformatory institutions were assigned to the Department of Public Welfare. The purchase of supplies and equipment and the power to erect or repair buildings were vested in the Department of Public Works and Buildings, and to the Department of Finance were given broad powers of financial and budgetary control in all departments.

Since that time the authorities have been reorganized in many states. The administrative arrangements for state charitable and correctional institutions, as they were in 1927, could be roughly grouped into five principal types of programs: public welfare departments resem-

bling that of Illinois in the attempt to departmentalize (California, Colorado, Idaho, Massachusetts, Michigan, Nebraska, New Jersey, New Mexico, New York, Ohio, Pennsylvania, Washington); single authorities in the form of supervisory boards (Delaware, Georgia, Indiana, Louisiana, Maine, Maryland, Montana, New Hampshire, North Carolina); administrative boards, either unpaid or ex officio (Connecticut, Florida, Kentucky, Oregon, Rhode Island, South Carolina, Vermont, Virginia, Wyoming); salaried boards of control (Alabama, Arizona, Iowa, Kansas, North Dakota, Oklahoma, South Dakota, Texas, West Virginia, Wisconsin); two or more separate authorities (Arkansas, Minnesota, Missouri, Tennessee). Three states (Mississippi, Nevada and Utah) have never created any central authority.

Although the movement toward centralization has been widespread it has been limited to the governmental arrangements of the states, and there has been no effective approach toward greater uniformity and cooperation between or among states or between the central and local jurisdictions in the states. There is as yet no national system. Such organizations as the National Conference of Social Work, the American Prison Association, the National Committee for Mental Hygiene, the American Association of Public Welfare Officials, have done valuable educational work and helped to achieve a unanimity of view, promoted national conferences and stimulated interest on the part of officials and of members of the legislatures, but the results are still far short of what could be desired.

As a consequence of this lack of unified direction there remain a number of important questions awaiting further agreement. Whether all the administrative institutions, penal and charitable, should be centralized in one department, as was done in Illinois and later in New Jersey; or whether there should be, as in Massachusetts and New York, separate departments of mental diseases, of corrections and of charities or public welfare caring for the destitute separately from the other groups, are subjects on which discussion is by no means closed. All these services have certain problems in common, such as the provision of shelter, food, clothing and hygienic and decent living conditions, and they all need similar provision for the investigation and diagnosis of individual requirements. It may well be desirable to have a degree of flexibility in the use of the different types of institutions. It is, nevertheless, equally clear that their spe-

cialized tasks vary greatly and call for the services of persons professionally equipped in different fields: the mental expert, the physician, the nurse, the teacher, the prison administrator, the dietitian and nutrition worker, the occupational therapist and so forth. Another problem on which agreement does not exist is the degree to which the separate institutions should serve the agencies in the local units or should be the instrumentalities through which the central authority secures such treatment as its diagnosis would suggest. This is perhaps a wider question than that of institutional organization. Shall the county authorities commit an insane person to an institution or to the department? Shall the juvenile court commit a delinquent child to an institution or to the department? Shall the criminal court sentence a guilty defendant to an institution or commit him to an authority? The relationship of institutions for the education of blind and deaf youth to the central authority involves another problem of jurisdiction. The origin of these in the provision for young persons from lower income levels and the fact that relief in the form of transportation and clothing is provided by public money have led to their being included in the general welfare structure. The teachers in these institutions, however, have frequently urged that they be universally regarded as part of the educational organization. Concerning these questions much greater unanimity may be expected in the future.

At a time when neither domestic nor institutional management had been placed on a professional basis, when cost accounting had not yet been developed, when the budget had yet to be accepted as a necessary device and central purchasing was an untried experiment, the rapid increase in the number of public positions and in the amounts of public money to be expended resulted in great waste in the use of public resources and great temptations to the corrupt and selfish. The situation was brilliantly and comprehensively summed up by Samuel Gridley Howe in 1866 in his first report as chairman of the Massachusetts Board of State Charities. Since that time the adoption of a budget and provision for some form or degree of cooperation, if not centralized purchasing, have characterized the development of institutional care in all the states. With regard to personnel the use of competitive examinations after the pattern set by the United States Civil Service Act of 1883 has been followed in ten states (California, Colorado, Illinois, Kansas, Maryland, Massa-

chusetts, New Jersey, New York, Ohio and Wisconsin). Other states resort to classification and to statutory descriptions of required qualifications for selected positions.

The Bureau of the Census has prepared several special reports which provide some illuminating figures concerning the number of inmates and the cost of their care in state institutions. Between 1910 and 1923 the number of hospitals for mental patients in the United States increased from 366 to 526. In the former year there were 143 state hospitals caring for 159,096 patients; in the latter, 165 caring for 229,837. Of the patients in these hospitals 34.2 percent, or more than one third, had passed ten years or more in such an institution, and 13 percent twenty years or more. In 1922 with an average daily patient population of 225,685 the per capita cost for maintenance in 153 mental hospitals was \$282.13 a year. The corresponding figures for 1928 for 159 hospitals were an average daily patient population of 264,484 and a per capita cost for maintenance of about \$309. If the costs for the services of the 23,788 nurses and attendants, 1223 physicians, 670 occupational therapists and 153 social workers be included, the total per capita cost for operation and maintenance becomes about \$360.

In 1928 there were 73 state institutions for the feeble-minded and epileptic. Reports received from 71 of these institutions showed 68,269 inmates in 1928 as compared with 66,444 in 1927 and 47,337 in 1922; during 1928 there were admitted 11,169 as compared with 10,224 in 1927 and 8565 in 1922. There was a marked decrease in the per capita cost of operation and maintenance during this period. In 1922 with an average daily resident patient population of 43,674 in 58 institutions the per capita cost was \$414.76; in 1927 the figures for 65 institutions were 57,104 and \$392.71; in 1928 for 67 institutions they were 61,295 and \$388.49.

The census reports 100 state and federal penal institutions in 1928, under whose control there were at the beginning of the year 109,346 prisoners, of whom 4363 were women; during the year 67,769 were admitted (3784 women) at a total cost of \$29,298,641, of which \$11,043,060 was paid in salaries and wages, \$6,594,671 for provisions. With an average daily population of 91,305 the per capita cost of state and federal penal institutions during 1928 was \$320.89. Figures for other groups, such as children under institutional care, paupers in almshouses or prisoners and juvenile delinquents,

are also easily available from the census reports.

An interesting feature of the cost of institutional services is that although they are considerable they are constituting a relatively smaller percentage of public expenditures, especially as compared with those for schools and highways. The total state expenditures for charities, hospitals and corrections increased from \$89,189,400 in 1915 to \$215,627,016 in 1929, but in 1915 they represented 23.5 percent of all state expenditures and in 1929 their percentage had dropped to 16.6. In 1915 the percentages for schools and highways were 38.5 and 6.0, and in 1929 they rose to 39.8 and 16.9 respectively (United States, Bureau of the Census, *Financial Statistics of States, 1929, 1931*, p. 26, 28).

With the increasing numbers of institutional inmates there has been a growing demand that treatment in each case be adapted to the actual needs of the individual patient and directed both toward mitigating the effect of his particular handicap and toward lessening any social disadvantage associated with it. The development of professionally equipped social workers makes this more possible, and although it entails greater expenditures and somewhat more elaborate organization it also results in greater economy and decrease in human suffering. Institutional custody is not always desirable or even necessary; a complementary service can be rendered by supervisory agencies which make possible approximately normal life in the community for many "wards of the state" who at an earlier date could have been cared for only in institutions. The idea of treatment has always been present to some degree in the case of the insane and the sick; for the mentally deficient, the blind, the deaf and the young offender education as well as custody is now being provided; and in the case of delinquent boys and girls and adult prisoners there is usually some effort toward reformation. Mothers' pensions and foster homes for dependent children, probation for the delinquent child or adult, parole for the adult prisoner or mental patient, are illustrations of the way in which a professional public social service can complement the work of institutions.

PRINCIPLES AND HISTORY. The theoretical treatment of insurance in American economic literature differs from that in European, particularly German, literature. Many outstanding American writers consider insurance as only one of the numerous risk covering agencies and therefore give inadequate or primarily legalistic definitions of its functions. Elsewhere this point of view is not generally held; with Germany as its center of growth, insurance has developed as an independent discipline distinct from other fields of economics and as such has received separate and extensive treatment. There is, however, general agreement among most economic theorists that the essence of insurance lies in the elimination of the uncertain risk of loss for the individual through the combination of a large number of similarly exposed individuals who each contribute to a common fund premium payments sufficient to make good the loss caused any one individual. Therefore before insurance can be undertaken on a sound economic basis not only the nature of an insurable risk but its probable occurrence and resulting loss must be determined.

It is obvious that all risks are not equally subject to indemnification by means of insurance. The chance or the uncertainty as well as the measurability of various types of risk differs. From an insurance standpoint there is no risk

unless there is uncertainty or, to use a better term, fortuitousness. It may be uncertain whether the risk will materialize in any particular case. Even death may be considered fortuitous, because the time of its occurrence is beyond control. Pure risks, such as hail or storm, cannot be produced deliberately by human agency; but there are many risks, such as fire, burglary or suicide, in which deliberate speculative causation can play an important part. Insurance as such, however, ceases to exist when more than the expected need is covered; that is, when a profit is consciously and deliberately planned for. In such cases insurance partakes of the elements of betting or gambling. This characteristic would be still more obvious were an individual to insure against someone else's risk and profit by its occurrence. There must always be the possibility, however remote, that the hazard will cause personal and direct loss to the insured, who must have, in legal phraseology, an insurable interest.

To secure a minimum of accidental over-insurance or underinsurance it must be possible to measure statistically the probability of the occurrence of the risk. The hazard must belong to a class large enough to conform to the theory of probability and to be calculable according to the law of averages, as must also the amount of coverage required and the number, magnitude

and duration of the premium payments. For two individuals to afford each other mutual protection would not be insurance; the law of large numbers would not apply and the degree of uncertainty would be too great. But when many thousands of persons or houses are considered, the risk and the future financial requirements are measurable once human ingenuity has devised a suitable technique, an actuarial science, for this purpose. In order that these future financial demands shall be met, however, certain economic conditions are prerequisite, such as the existence of a unit of value and suitable means of accumulating wealth through extensive capital investments. This does not mean that coverage has to be provided in money; it may take the form of goods (medicines, cemetery plots) or repairs (automobile or house repairs) or services (medical aid or legal assistance), depending on the type of hazard or risk.

The risk itself may involve a direct loss (burning down of a house), loss of profit (destruction of crops by hail or interruption of business), loss of capital (bankruptcy), loss of income (unemployment or strikes), the cessation of ability to save (advanced age), expenditures to avoid a threatened loss (prosecuting a liability case) or planned expenditures (endowment for a college education). In all these cases there exists a need for money or for the equivalent of money produced by a risk of some sort. Although risks

such as embezzling and the guaranteeing of mortgages are not pure insurance risks, they are generally considered so by statutory authorities.

The three principal branches of insurance—life, fire and marine, and casualty—may for convenience be grouped according to the interests insured, that is, coverage of tangible and intangible property risks and of personal risks, as in the accompanying classification. The practise of insurance companies, influenced as it is by tradition and statutory regulation, does not always follow specialization by forms as enumerated below. On the other hand, a more detailed analysis would show that each of these forms represents a variety of separate risks.

There is a fundamental distinction between the type of loss which life insurance and health insurance attempt to cover and other losses. If a house is damaged by fire or crops are harmed by storm, there is ordinarily some objective measure of the loss, and only this actual loss or a percentage of it is made good. In other words such insurance operates in greater or less degree as a contract of indemnity. But when an individual's life or earning power is affected no accurate measure of its value is possible. The insurance contract therefore assigns the risk a fixed value, which is all that the insured receives when the policy falls due.

The economic function of insurance is not the elimination of risk or loss—although insurance

CLASSIFICATION OF INSURANCE FORMS

| PROPERTY INSURANCE | | PERSONAL INSURANCE | | | |
|--|----------------------------|--|----------|----------------------|-------------------------------|
| LOSS RESULTING FROM IMPAIRMENT OR DESTRUCTION OF | | LOSS OF INCOME OR INCREASED EXPENDITURE DUE TO | | | |

| Boiler and machinery | Reinsurance | | | | |
| Plate glass | | | | | |
| Depreciation | | | | | |

organizations may find it profitable to engage in this activity—but rather the substitution of a known small loss for an uncertain large loss. The implications of this function are not as negative as they at first appear. Society as a whole benefits through the accumulation of capital reserves which make good the loss resulting from the destruction of valuable assets; business costs are lowered to the degree that risk is eliminated and credit strengthened; and the insured individual is enabled through mutual action to obviate poverty and destitution for himself and his dependents. The fact that the payments of all participants aid each participant in case of need is an essential characteristic of insurance. This principle of mutuality is not limited in the slightest degree to mutual companies but applies to all insurance organizations whatever their legal structure, to stock companies as well as to government insurance funds. The more numerous the individuals of each class who share the risk, the more exactly can it be estimated and the more cheaply can it be covered and protection administered. It is precisely because insurance is mutual that public opinion, even in states predominantly capitalistic, has almost universally caused the governments to abandon the theory of individual initiative in favor of compulsory insurance of risks such as health, workmen's compensation and fire.

Insurance has not been possible at all stages of economic development, nor is it probable that there will ever exist insurance for the coverage of all conceivable risks. In addition to such obstacles as an insufficient knowledge of the facts there may be an inadequate capacity for organization or legal and religious prohibitions, such as the ban on the taking of interest. The concepts of prerequisite conditions have changed considerably in the course of time; experience has shown that an imposing structure can be erected upon foundations which were considered inadequate in less highly developed periods; technological advance has brought with it new and formerly unknown hazards to life and property. Modern life is surrounded by a vast number of latent dangers produced chiefly by the harnessing of natural forces whose direction is entrusted to fallible human beings. On the other hand, even when all the technical conditions have been met, insurance will not be realized if there exists neither an economic need among a sufficiently large number of people nor the desire or the financial ability to make use of it. To the prerequisite conditions for the development of in-

surance might be added certain subjective limits arising from the ethical outlook of the individual and of his social group.

The history of insurance is as yet unwritten: only milestones of its evolution are known. Devices resembling insurance were not unknown in antiquity. In imperial Rome, for example, there existed *collegia*, associations of artisans, which paid the surviving dependents of their members a funeral sum in return for the payment of an initiation fee and monthly premiums. Loans on bottomry were common. Few such institutions of antiquity, however, survived into the Middle Ages. In most of the early mediaeval insurance institutions (funds for freeing comrades from imprisonment, for mutual bearing of losses due to fire or the death of cattle and for replacing cattle stolen from members of a guild) groups of persons joined together because of common interest. But with the sense of common interest both within and without the guild funds there was associated the acquisitive instinct to which modern insurance owes its origin, its entire development and its beneficial effects. The origin of insurance as a profit making business lay not so much in the guild system as in Italy's marine insurance trade, which began about the middle of the fourteenth century. Here the early phase of insurance ends. The first period of its evolution proper, characterized by the introduction of the insurance contract, lasted until the end of the seventeenth century. The second period, marked by the founding of insurance stock companies, includes the eighteenth century and the first half of the nineteenth. In the third period, which comes down to the present day, social insurance developed alongside individual insurance, while the latter, expanding everywhere beyond the boundaries of the several countries and continents, evolved into big business. In this general evolution there can be distinguished three types of insurance operation, more or less independent, not successive but rather passing often and continuously from one type to another. These three types may be called cooperative, capitalistic and governmental.

The organization of insurance on a cooperative basis is motivated by the same causes and follows essentially the same development in modern times as in antiquity. The capitalist type of insurance, the insurance business proper, was born of marine insurance, which, of Roman origin, was founded for profit and based on commercial calculation. Fire insurance, on the other hand, arose by the beginning of the six-

teenth century in Germany as a communal undertaking, developing thereafter partly as a governmental institution and partly as a business. The capitalism which characterized the second period of growth beginning with the end of the seventeenth century is expressed in the development of stock insurance companies. The first precursor of the modern insurance concern was a short lived marine insurance company founded in 1668 in Paris. Two marine insurance companies founded in England in 1720 are still in existence. In Germany the first corporation for marine insurance was founded in Hamburg in 1765 and another concern of the same type was founded during the same year in Berlin. Life insurance in its present form arose almost a hundred years later than marine and fire insurance of the modern type because of the fact that life insurance is built upon more scientific foundations. There was no mathematical statistical mortality research, essential to the modern life insurance company, before the end of the eighteenth century. Its development was moreover impeded by the legislation of previous centuries, which forbade the taking of interest, gambling or betting and which—not always unjustifiably—viewed life insurance as a bet or as a dangerous gamble because of its almost criminal excesses. The last third of the eighteenth century witnessed the rise of hail insurance and cattle insurance as aids to the new intensive agriculture.

The highly differentiated economic life of the second half of the nineteenth century brought with it numerous cultural gains accompanied by new dangers and new requirements: the growth of railroads; the increase in factory production and the liability of the entrepreneur; improved methods of building, especially the wider use of glass windowpanes, the installation of water pipes in dwelling houses; the extension of credit and mortgages; the rise of the automobile and of aircraft. All these innovations made room for the spread of the idea of insurance. Accident insurance was introduced in 1845 and liability insurance in 1876; these were followed by glass insurance, insurance against damage to water pipes and so on. Corporate fidelity bonding was first practised in 1840, title insurance and credit insurance developed in the 1890's, workmen's compensation met the need of statutory requirements of the early twentieth century and public liability insurance, especially of automobile risks, has expanded rapidly in the last decade. The expansion of the insurance industry made

necessary in turn the extension and spread of re-insurance, which more and more displaced co-insurance. But the new epoch is even more clearly characterized by the growth of the insurance companies into enterprises operating on an international scale, by the founding of subsidiary companies and by the formation of cartel-like associations of entrepreneurs in all large countries and in all branches of insurance.

The introduction of social insurance proved an influential factor in the development of insurance during the last half century and has been most extensively developed in the various branches of personal insurance. Social insurance is not so much a new principle as the combination of various elements which may be found separately in individual insurance, whether private or mutual: compulsion, the establishment of monopolistic state funds, partial support by treasury funds and more distinctively the levy upon employers for premium payments. Social insurance originated in Germany and is closely connected with the name and the policies of Bismarck, who introduced sickness insurance in 1883, accident insurance in 1884 and disability and old age insurance in 1889.

A new era of growth began with the end of the first decade of the present century; new general insurance companies were formed for the writing of branches of insurance which previously had been undertaken separately. In addition numerous unions of local insurance societies and of those limited in membership were organized, leading increasingly to that more general distribution of risks which is especially advantageous for insurance. The World War did not exert as destructive an effect upon the position of insurance in economic life as might have been supposed, and between 1918 and 1923 more new companies were founded than in any previous five-year period. The effect of the post-war inflation period was catastrophic, but the successful stabilization of currencies brought with it to an astonishing degree a rapid and extensive growth of insurance. Horizontal concentration to reduce competition has been especially characteristic of this period. But vertical concentration, for instance, in the form of the combination of insurance and reinsurance within the same concern, is not uncommon. The increasing importance of the insurance industry has everywhere resulted in legislation leading to more effective state supervision of its conduct and its policy forms.

INDUSTRY. In any survey of the modern economic world the business of insurance must have a prominent place. In the United States, where insurance is probably more extensive than in any other country, the aggregate insurance premiums of all classes of carriers for all types of risks is nearly \$6,000,000,000 annually; yet even in this country the full potential development has not been approached. Some American and more particularly English companies do an extensive foreign business in various parts of the world; today there are local companies even in such relatively undeveloped regions as the Fiji Islands. Moreover in many European countries governmental systems of social insurance are even more important than private systems.

By its nature the insurance business is a quasi-public utility. To be effective it must deal with large numbers of individuals, few of whom have any clear idea as to its fundamental principles. Through inequitable treatment harm might be done large classes of policyholders and unfair advantages be given others. And while it is possible to carry on a limited insurance service on the assessment principle, extensive operations require advance collection of premiums and sometimes, as in life insurance, the collection of at least a part of the cost many years before requirement for loss payment. Thus arises the need of wise conservation of unearned funds in reserve for future expenditure. For this reason most governments have assumed greater or less powers of supervision of the investment policies, rates and related aspects of the insurance business. While the industry has not yet been generally required to undertake the responsibility imposed on public utilities of justifying to a public authority its refusal to serve any who apply, this requirement, dangerous in insurance because of the intangibility of moral hazards, has been imposed in a few cases.

In the development of the insurance industry several types of carriers have received recognition of supervising authorities. None has yet proved so superior as to warrant acceptance as the one proper type; and only one, the individual underwriter acting alone, has passed from the stage. It is difficult to visualize a new type more effective than any yet developed; nevertheless, it might be unfortunate if supervision should cause such standardization as to preclude this possibility. Any new development must necessarily be surrounded with adequate safeguards for the public to whom it may offer its services. By a wise choice of carrier the insured may often

gain distinct advantage; not all types are suited to every condition, and careful discrimination is important. The tendency on the part of the insuring public in the United States to rely too greatly on a government license as a guaranty of safety imposes a distinct limitation on the range of permissible experiment.

Existing types of carriers fall into three general categories: proprietary, cooperative and governmental. In addition, notice may be taken of self-insurance. There is a real distinction between non-insurance and true self-insurance. Under non-insurance risk is not eliminated by artificial means, although extensive operations involving separate risks may bring about considerable regularity in loss occurrence. True self-insurance involves the establishment of a fund into which regular payments are made and from which losses are paid. Self-insurance is practicable only when the operations of the self-insurer are so conducted that a large number of independent risks are present, such as would be brought together through the operations of a professional risk carrier. The workmen's compensation and public liability risks of a metropolitan street railway system are examples of those suitable for self-insurance treatment. But even in this case the fund should be protected by an adequate surplus or reinsurance against an unusual concentration of losses in a brief interval of time.

There are two types of proprietary insurance carriers: individual underwriters, operating in syndicates, and stock corporations. Under careful supervision, such as is exercised by Lloyd's of London, underwriting syndicates have proved satisfactory as carriers of short time risks. Indeed they have furnished for centuries and still furnish a major part of the marine insurance of the world. They are not suited for and have not attempted the long time coverage of life insurance. The chief drawback in dealing with members of underwriting associations is the uncertainty of continuous financial responsibility except in cases where somebody, such as the Lloyd's committee, has power to use adequate pressure to assure it. Stock corporations have proved satisfactory carriers in all fields of insurance, although they are not per se proof against mismanagement. With adequate regulation and in some countries with merely enforced publicity of accounts and transactions only reasonable care on the part of the insured has been necessary to maintain his safety. In the United States the most serious criticism is that expense of operation is excessive, primarily because of the

cost of acquiring business under a competitive system which employs agents paid by commissions on premiums.

There are three distinct classes of cooperative risk carriers: first, friendly societies (*q.v.*) or fraternal orders (*q.v.*); second, mutual corporations; third, interinsurance, or reciprocal, exchanges. The distinguishing characteristic of the first group is the operation through local lodges which are also centers of social activity. Such lodges have generally confined their insurance activity to life insurance and the granting of disability benefits. Until recently they have tended to ignore actuarial principles and consequently have been forced to make painful readjustments. Low cost and social attractions have constituted their chief drawing card.

Mutual corporations may be subclassified according to their reliance on the assessment of members or on advance premium collections for the payment of losses. Even when reliance is placed principally upon assessment, it is the usual practise to collect a sufficient sum in advance to pay losses in the interval between assessment periods. Assessment is practical only for carrying risks closely uniform in kind and degree; it fails utterly when these conditions are lacking or in cases of progressive risk, as in life insurance. Its chief advantage is low operating cost because of simplicity of organization. The advance premium system, on the other hand, may or may not have coupled with it a supplementary assessment liability of the policyholder; in life insurance on an actuarial basis such provision is not common. The advance premium is usually more than adequate and excesses are refunded through so-called dividends. Since advance premiums in both stock and mutual systems must be conservatively determined to assure adequacy, mutual companies have the advantage of more accurate subsequent adjustment to actual cost. Except in life insurance, where the agency methods are similar to those of the stock company, lower costs are frequently realized usually by virtue of lower operating costs, principally acquisition costs; sales staffs work either on a salaried basis or on a lower scale of commissions than do the representatives of stock companies. In contrast dividends paid by the mutual life insurance companies derive mainly from interest in excess of that assumed in the actuarial calculations as well as from savings in mortality. The loadings by which gross premiums are derived from the net premiums found by actuarial calculations frequently contain a

margin for dividends, which in times of emergency may also be a safety factor. Mutual companies outside the life insurance field, in which they predominate in America, have been most successful in acquiring highly protected manufacturing risks for fire insurance and workmen's compensation insurance and isolated dwelling and farm buildings for fire insurance. In the large companies where the policyholders control in name only the high salaries paid the officers have taken the place of profits as an incentive to efficient operation.

Interinsurance exchanges are unincorporated groups of individuals reciprocally insuring each other and operating through an attorney-in-fact who is given a power of attorney by each member in the course of his application. In general, advance "deposits" are made by the several members against which the members' proportion of losses and expenses are charged. Periodically an adjustment is made by refund of balances or collection of deficiencies. While the attorney-in-fact is usually invested with full powers to do anything necessary for the conduct of the exchange he is not personally responsible for the results of unwise underwriting or loss adjustment. When the exchange is managed by a competent and honorable attorney-in-fact and membership is confined to the financially responsible with substantially similar risks, such exchanges have proved satisfactory carriers and have operated at low cost. In a number of cases, however, the plan has been subjected to grave abuse by irresponsible and dishonest individuals, who set up exchanges under their attorneyship and offer coverage to the general public without adequate explanation of the nature of the carrier.

Governmental carriers, that is, state insurance funds, are of two types. The term is applied, on the one hand, to a self-insurance fund for carrying risks to which the state and its subdivisions are exposed and, on the other, to state institutions set up to act as insurance carriers for the risks of its constituents. In the field of non-compulsory life insurance—which experience indicates must be sold energetically—they have written little business but have operated at very low cost. Where for reasons of state policy insurance has been made compulsory, it has been argued that the state must set up a carrier in order to provide insurance at the lowest possible cost. Sometimes the state fund has been given a monopoly of its field, as in certain European social insurance systems and in workmen's compensation insurance in some of the states of the

United States. In other cases the funds are competitive. Although they have at times been the victims of political abuse they have as a rule furnished sound insurance at low net cost because of low operating cost. Organization has in general followed the lines of private mutual corporations; save that a government board or bureau takes the place of the board of directors elected by the policyholders.

All insurance carriers except the simplest assessment type have certain common problems. Premium rates must be established for each class and degree of risk assumed; an adequate volume of risks must be procured to give a reasonable stability to the mass; and the company must be safeguarded against adverse selection and too great concentration of risks. Such work is known technically as underwriting. Premiums received in advance of requirement for loss payment must be conserved and suitably invested. Losses must be investigated and settled fairly. In addition every carrier has a large amount of detailed clerical accounting and statistical work calling for an elaborate and highly organized staff.

The problems of rate making and underwriting are closely associated. The economic function of insurance is the substitution of a fixed charge for an uncertain risk by transfer of that risk to a professional risk carrier who may thus acquire mass stability, with a consequent equitable redistribution of the losses and the expense involved. Thus the insurance contract must be a contract of indemnity—life insurance policies are to some extent an exception because of the impossibility of accurately appraising life values—and the rate must be equitable. The test of equity is that the individual insured should so far as possible pay only what would be his proportionate cost in a sufficiently large company composed exclusively of risks identical with his own. Precise equity is probably unattainable, but the aim of all rate making practise and procedure is approximate equity. In a competitive situation countenance by a carrier of substantial inequity carries its own punishment. The general rate level rarely gets high enough to yield more than a modest underwriting profit. If overcharged risks do not seek insurance elsewhere, forming if necessary new mutual carriers, competition of carriers for the "preferred" business augments acquisition expenses and reduces the margin of profit. The losses on the undercharged risks are then unbalanced and the guilty carrier is correspondingly weakened.

Although rates must be made for the future

they can be based only on past experience. Changes in condition, especially in long time trends, must be carefully observed; as, for example, the effect on accident rates and consequently upon costs of workmen's compensation of increasing mechanization of industry. Varying with the type of coverage the making of rates involves statistical study of experience, engineering technique and trained judgment of experienced underwriters. Seldom if ever is even a single carrier's experience broad enough to form a safe basis of rates. Moreover, since competitive bargaining over rates is disastrous, rate making can never be wholly an individual company matter but must always remain a group problem. The safeguards for the public are publicity in methods and in some cases direct or indirect public control. Since the rate must cover expense as well as loss cost, control of rates implies control of expenses. Sometimes, as in life insurance, the return upon invested funds must also be considered; but generally it is not possible to determine underlying probabilities with sufficient precision, and investment profits have been left as the source of return to stockholders.

The acquisition of an adequate volume of business presupposes an effective selling organization. Such organization is usually a blend of three types of systems: direct reporting, branch office and general agency. The first involves direct contact between the head office and the individual members of the sales staff, who may be paid by salary or commission, and is not adapted to complex conditions or to operations extending over a large area. It is used only by the simplest types of carriers operating over a small territory or by larger organizations for the region closely adjacent to the home office. Under the branch office system subordinate offices are maintained at central points in the charge of salaried officials of the company, whose compensation may be supplemented by a share of the profits from the business in their territory. In some cases the activities of the branch are limited to sales efforts and closely associated duties. In others the full range of operations (except investment of funds) is carried on in the branch office and only summary reports are made to the head office. The contacts with policyholders are maintained through local agents or brokers. This form of organization is best adapted to a well established company which has already developed a large volume of business in the territory. Under the general agency system contracts are made with individuals or firms for the

development of extensive territories. The general agent under such restrictions as his contract provides builds up and supervises his own organization of local representatives. He usually finances himself in this work and his profit is the difference between his commission and the sum which he pays local representatives and brokers. In fire and casualty insurance he has at times some powers and responsibility for loss settlements in his territory. In these fields he may have authority also to represent his company in rate making and other regulatory bodies.

Brokers are independent experts offering their services to the public in insurance matters. In marine insurance they are indispensable. While they represent the applicant in negotiations for insurance they obtain their compensation from the companies in a commission on the premiums paid. When they are given policies on order to deliver and collect they become the agents of the companies for that purpose. In life insurance policies are issued only at head or branch offices and the agent merely takes the application and delivers the policy. It is the usual custom in fire and most casualty lines to supply the agent with blank forms authorizing him to issue the policy and to report the facts to his supervising office. In the United States an insurance agency is often combined with a real estate office or other business, although strong efforts have been made by life insurance agents to eliminate the part time agent.

The American business man does not as a rule deal directly with insurance companies. If he is not solicited he usually takes his risk to an agent or broker, leaving to him the selection of a company. In fire and casualty lines agents frequently represent more than one company. Consequently competition between carriers tends to be a competition for those agents who can turn in the most business. This competition centers on rates of commissions, prizes and other allowances to agents and brokers. On the other hand, high commissions tend to bring about overselling, with a consequent high lapse rate; this has proved an unfortunate characteristic of the life insurance business, involving a serious economic waste. Excessive commissions also lead to rebating and other unfair practises which are difficult to control by statute. Moreover even the insurance of property values involves the intangible personal element as an important part of the hazard. All risks offered therefore must be carefully investigated. Where the insurance policy is issued only by head or branch offices, the

company may be safeguarded against excessive hazard by rejection of an application or by offering insurance only on special terms or at increased rates. Where the agent is authorized to issue policies he may be controlled to some extent by instructions. The final safeguard is exercise of the right of cancellation reserved to the company in the policy contract. Brokers are at times able to exert improper pressure upon agents and through them upon underwriters by offering a mixture of good and poor risks and insisting that if these are not accepted in toto the entire business will be placed elsewhere and other good business will be withdrawn upon expiration of the current policies. More or less effective efforts are made through company associations to control such competition. But it is extremely difficult to do so through purely voluntary associations and in some cases, particularly in the United States, it has been necessary to place statutory limits on commissions.

Underwriters must also consider the matter of concentration of risk. Insurance began among traders and in the cities and the chief demand for insurance still comes from the great metropolitan centers, where values are so congested and exposed to common hazards that careful underwriting calls for the retention of relatively small net lines. This involves the fixing of a maximum limit on the amount or "line" which will be carried on an individual risk and often the fixing of supplementary limits for groups of risks which may be exposed to loss from the same event. Hence there is apt to be in those centers an unsatisfied demand for insurance which tends to bring about the establishment of new carriers. These new carriers, however, cannot find an adequate volume of satisfactory business in large cities alone; they seek to diversify and spread their risks by conducting their activities in the smaller communities, where unit values are smaller and the extent of common exposure not so great. Here there is a larger underwriting capacity than necessary, involving the severest competition, which can be held within safe bounds only by wise cooperation, not merely for rate making but also for the regulation of agency relations and other practises. Regulation is exceedingly difficult to maintain unless it is required by law. The history of each branch of insurance in the United States is largely a record of efforts to maintain such organizations. The problem has been made the more difficult by the fact that insurance has been held not to be commerce and is therefore not subject to federal

regulation. The several states have not been consistent in their views, particularly on this matter of combination. At first the theory generally held was that it was an improper restraint of trade and should be suppressed. Many anticomcompact laws were the result. More recently a better understanding of the business and its problems has led to the repeal of many of these laws and in some cases to the requirement of combination under state supervision. But not all anticomcompact laws have been repealed, and many carriers are required to conduct their business in one state in a manner which in another would subject them to severe penalties.

In some fields, as in workmen's compensation, it is impossible to fix limits on the risks written, since public policy demands that all employees be insured for the full statutory benefit. It is also desirable at times to accommodate agents by assuming more than the fixed line on an individual risk. Groups of individually acceptable risks may give rise to excessive group lines. The carrier can protect himself in such situations by reinsurance. Although there were sporadic instances of reinsurance in the early history of insurance, the practise necessarily became more widespread as values presented to the carriers for coverage increased either individually or by concentration. The latter half of the nineteenth century witnessed the formation of a number of companies devoted exclusively to reinsurance. Such companies offer either facultative contracts or treaties; most reinsurance is now handled by the latter method, practised also by companies which do not confine their operations exclusively to reinsurance. Under the facultative method the direct writing company is not required to cede and the reinsurance company is not obliged to accept any particular risk. If the reinsurer is offered a risk, however, he is bound to it until he declines. Under an automatic excess treaty the direct writing company is bound to cede and the reinsurance company to accept all excesses falling within the classes stipulated. The treaty usually provides that the excess covered shall not be greater than the net retention of the original company; in order to be fully protected and yet offer its agents the opportunity to cover their clients adequately a direct writing company often arranges several treaties covering successive excesses. As a rule the coverage of the reinsurer is identical in terms with that of the direct writing company and transactions are reported periodically by a tabulation or *bordereau*. Companies writing such risks as workmen's

compensation protect themselves by a reinsurance treaty which covers losses on any risk from a single event in excess of a fixed limit and up to a secondary limit. Under such a contract, the premium for which is a fixed percentage of the total premiums for that kind of risk written by the direct writing company, there is no need of reporting individual risks. The amount of premiums is determined and paid periodically. Reinsurance carriers are subject to sudden increases in the amounts they have at risk in particular locations or on individual risks and must have the means of divesting themselves promptly of dangerous excesses. They must in turn arrange reinsurance facilities; many of these arrangements are international and large risks may ultimately be spread among carriers throughout the world. Young carriers with strong backing and good agency connections, finding the financing of a large volume of business too expensive, frequently arrange for quota share reinsurance of a fixed percentage of all business they write. When a fleet of carriers in a single field, such as fire insurance, is under the same management because of interlocking control, quota share pooling of all the business of each of the carriers is not uncommon. Similar reinsurance pools may be formed by independent carriers operating in the same line.

The public interest requires that in general the insurance policy be a contract of indemnity and from this arises the problem of loss adjustment. This problem is relatively simple in life insurance, since all policies are for fixed values and only total losses are encountered. In other fields it is most difficult to determine the carrier's obligation. The insured rarely reads his policy before a loss, and despite most careful definition therein of the risk assumed and the procedure for determination and settlement of losses he may have an exaggerated idea of his rights and none of his obligations. Overpayment of losses tends to lessen the interest of the insured public in the prevention and minimizing of losses. It not only tends to increase the cost to all policyholders but it invites fraud. The avoidance of overpayment is an obligation of an insurance carrier to its policyholders as a group. But the public renders all too little support to the companies, since it is commonly assumed that insurance companies like public service corporations are fair game. Thus the agents of the company which acquires a reputation for niggardliness and insistence on technicalities find it difficult to carry on. Because of the pres-

sure for liberality, not to say laxity, in loss settlement the adjusters are placed in more or less of a dilemma. In general the policy of representatives of well managed carriers is governed by their estimates of the good faith of the claimant. Where fraud is suspected, every technicality is insisted upon. If misunderstanding of obligations is accompanied by evident good faith, technicalities may be waived and values liberally estimated, so that policy provisions as to disinterested appraisal are invoked only when agreement is apparently impossible otherwise.

The need for conservation of funds during the interval between their receipt as premiums and their disbursement for losses and expenses creates the problem of investment. The normal length of this interval and the time and manner of loss payment are the determining factors in setting investment policies. Both vary materially with the type of coverage.

Fire and marine insurance provide coverage for relatively short intervals. The nature of the potential demand for funds requires that investments be quite liquid, for there may be need of large sums on short notice. Although reserves need be held only for losses in course of settlement, unearned premiums and incurred unliquidated expenses, wise management calls for the accumulation of considerable surplus. Total assets, of which about 85 percent are invested, aggregate in the United States a little less than three times the annual premium income. For most casualty lines the conditions are generally similar; but in some, for example liability insurance, the time required to determine the company's liability in particular cases provides an interval during which cash reserves may be built up out of current income. Large workmen's compensation losses may be incurred through single events, but the fact that benefits are payable over considerable periods of time slightly relaxes the need for liquidity. The reserves for unliquidated losses in casualty and compensation insurance are much larger than in fire and marine.

In life insurance reserves assume the greatest importance. The life insurance contract usually covers a long term of years. But because the premiums remain level throughout the term, the payments exceed the risk cost and the difference, the unearned premium, must be held by the company in the form of reserves which act as self-insurance to reduce the net amount at risk and thus compensate the increasing risk. Life insurance companies thus accumulate vast sums

for investment. Even in the United States, where the proportion of recent business is large in all companies, the assets at the present time exceed five times the annual premium income. If a company has a substantial premium income it has little need for concern with liquidity in investments. Security and regular yield are the prime requisites, the latter by reason of the necessary assumption of interest income in rate calculations.

Investment policies are controlled by the directors of the several companies. Unfortunately these directors, who are usually engaged in other businesses, have not always respected the trustee character of their reserves as guaranties of their contracts but under the guise of investment have indulged in speculation. At times this has been merely bad judgment but there have been instances of improper use of company funds for the advantage of officers, directors and others having a close relation to the companies, and some failures have resulted with loss to policyholders and stockholders. This has led to government regulations and restrictions with respect to investment policies. Theories and methods of governmental interference in investment activity differ widely. At one extreme is the British system of freedom of action with the requirement of full publicity and only minor prohibitions, such as those forbidding investment of life insurance funds in the shares of any insurance undertaking except with the consent of the court. At the other extreme stand Germany and some of the states of the United States, which prohibit definitely some classes of investments and restrict the proportion of funds which may be put in others. Under the German law, for example, stocks to be eligible must be listed on a German bourse and not more than 10 percent of the reserves may be so invested. Intermediate perhaps are those states which leave the field fairly open but require periodic reports and vest in an official of the state authority to require immediate sale of an investment which he does not regard as within the statutory category of first class securities. In general, only such real estate may be held permanently as is requisite for the convenient transaction of business. Other real estate may be taken on foreclosure of mortgages or otherwise in the satisfaction of debts but must be disposed of within five years unless an extension of time is granted by state supervisors. Investment in loans on personal security or so-called commercial paper is not permitted in the United States. Real estate mortgages, subject to

a set ratio to the value of the pledged property, are freely permitted. Government bonds and those of established private corporations are generally allowed. More restrictions are placed upon stocks, especially as investments for life insurance companies. Loans on security of stocks and bonds are generally permitted, at least on such securities as might have been bought. Officers and directors are generally prohibited from being interested except on behalf of the company in any such loans. Annual statements, including detailed schedules, from which the character of the assets and the investment policy may promptly be ascertained, are a universal requirement. Sometimes they must be published; usually they are filed as public documents open to general inspection.

In the United States alone the insurance carriers, with over \$26,000,000,000 assets and \$6,000,000,000 annual premiums, form an enormous collecting reservoir of investable funds. Their influence in the investment markets—for farm and urban mortgage loans, for bonds and stocks—is correspondingly important. In the autumn of 1929 no small amount of the loans of New York banks on stock market securities "for account of others" came from insurance carrier funds.

The qualities desired in life insurance investments—security of principal and fixity of yield for long periods—have caused their distribution over a period of years to vary between urban and farm mortgages, government, railway, utility and industrial bonds, in accordance with the state of the market and prospect of security and yield. Certain life insurance companies have until very recently confined their investments to mortgages, with a large proportion of farm mortgages, and built up extensive organizations for the purpose of handling such loans. The last quarter of a century has seen such an enormous growth in life insurance in the United States that recent discussions have shown some uneasiness regarding the adequacy of the volume of safe outlets for future investments. The need for fire companies to keep their portfolios liquid has caused a frequent turnover of their investments. Large profits have been made in rising stock markets and the companies have at times been suspected of speculating. It may be difficult to draw the line between speculation and proper safeguarding of liquidity in such times, as it is also difficult to find a just basis of valuation of insurance assets. Since bonds are bought by life insurance companies as permanent investments, it is ap-

propriate to value them by the amortization method, a practise which is prescribed in some states. Stocks, however, are not susceptible to valuation on the amortization principle and its application to bond investments of those classes of carriers subject to potentially heavy demands for ready cash is inappropriate. All investments of such carriers are properly subject to a market value test, which creates no little difficulty for supervisory authorities in times of declining markets. In the event of forced liquidation an insurance carrier usually sacrifices substantial but intangible values in agency organization. If the decline is temporary this should be avoided. The problem is to determine when the decline is permanent and whether it is safe to allow time for adjustment.

DISTRIBUTION OF ASSETS OF LIFE, FIRE AND CASUALTY COMPANIES OPERATING IN NEW YORK STATE AS OF DECEMBER 31, 1928

| | LIFE COMPANIES | FIRE COMPANIES | CASUALTY COMPANIES |
|---|----------------|----------------|--------------------|
| Real estate | 1.8 | 1.8 | 3.1 |
| Mortgage loans | 41.9 | 3.3 | 5.1 |
| Bonds and stocks * | 39.6 | 79.5 | 72.7 |
| Collateral loans | .1 | 1.3 | .9 |
| Cash, premiums in course of collection, accrued interest and like items | 4.5 | 14.1 | 18.2 |
| Loans to policyholders | 12.1 | | |

* The relation of bonds to stocks is as follows: life companies have relatively little in stocks, the investments of fire companies are divided about evenly, while for casualty companies bonds predominate slightly.

The essentially mutual character of the insurance industry has led to the establishment of numerous associations and to the forwarding of their common interests. The lack of general understanding of the fundamentals of insurance, the large amount of unwise legislation proposed in consequence and the difficulty of opposing it individually have led to intercarrier organizations for lobbying and propaganda. Although actuated by motives of self-interest such propaganda and lobbying have often worked to the public advantage. Carriers and their representatives have sponsored research in fire prevention, accident prevention and life conservation methods. They have cooperated with the law enforcing authorities in the suppression of arson and in other protective measures. High technical capacity is requisite for certain kinds of work re-

quired by insurance carriers; for example, the work of the actuary. While general educational institutions have long furnished the basic ground work for such capacity they have until recently not attempted the necessary specialized training. Associations of actuaries, insurance institutes and similar bodies have tried to fill this need with the encouragement and sometimes the financial support of the carriers. Their publications have furnished material for study, and examinations for admission have provided the incentive to such study. Since the turn of the century such activity has increased markedly, and with the introduction of curricula in commerce in the leading universities a growing number of courses on insurance are being given. Some of these are general, dealing with the economic aspects and services of one or more classes of insurance, principally fire, marine and life insurance. Others are technical, concentrating on actuarial science and fire or accident prevention engineering. As more broadly educated and better trained men become available for the management of the carriers and as the public acquires better understanding of the services and problems of insurance, there will undoubtedly be an even greater efflorescence of the industry.

A. H. MOWBRAY

LAW AND REGULATION embrace three groups of legal provisions. The law of the insurance contract although nominally based upon consent actually prescribes the rights of insurer and insured under a highly technical document with less regard for freedom of the will than for equalization of bargaining power between the parties, for the legal protection requisite to an effective selection and control of risks and for the social desirability of a widespread use of the insurance device. The law of insurance regulation, grounded in the state's police power over private enterprises, is designed to secure the financial safety of insurance carriers, their prompt and easy amenability to suit by the insured and the fairness of their business methods. A third group of laws prescribes the operations of the state itself or of a subordinate governmental instrumentality as a carrier of workmen's compensation and other social insurance. This group is highly developed in Europe but is restricted in the United States to state compensation funds, war risk insurance and minor state insurance schemes.

The antiquity of insurance has long been disputed. If the mutual aid associations of Greece

and Rome—usually recreational societies with incidental death benefits—are included, the origin of insurance may be traced to ancient times. In a sense the family may be considered a primitive type of mutual aid group. At any rate the benefactions of the early societies were apparently without legal sanction and their existence has left no trace upon modern insurance law. If, on the other hand, only the entrepreneur type of insurance organization is included, then insurance originated probably in northern Italy around 1300. The mediaeval Italian contract (*polizza*) was the earliest known form of insurance policy.

The insurance contract being a promise to pay a larger sum (the amount of loss) in exchange for the prior payment of a smaller sum (the premium) was thought at first to violate the canonical prohibition of usury. Hence the early contracts were disguised as pseudo-sales; that is, the insurer agreed to buy the goods from the insured only if they were lost at sea. When the usury ban ceased to be operative and these evasive devices were abandoned, the clumsy forms of early insurance policies (witness the Lloyd's marine policy) made possible their abuse as wagering devices by those who suffered no loss from the catastrophe insured against. Early continental legislation was aimed at this evil. In England marine insurance contracts, probably introduced in the early sixteenth century and first extensively used in the Elizabethan period, came during the early eighteenth century to be used as wagering devices through the insertion of the "P. P. I." (policy proof of interest) clause, by which the insurer agreed to dispense with proof of the insured's interest in the property insured. English courts, unwilling to create a rule against wagering and tolerant of the protection thus afforded to smugglers, enforced contracts in this form until 1746, when they were declared void by a statute (19 Geo. II, c. 37) which was later reenforced by criminal sanctions [Marine Insurance (Gambling Policies) Act, 1909]. In the United States most courts did not await the advent of legislation before declaring wagering contracts unenforceable. They fashioned from the Puritan and pioneer tradition of useful industry a judge made public policy against wagering.

To differentiate insurance from wagering the courts require an insurable interest, which in its broadest sense is any relation—other than that created by the contract—between the insured and the event insured against, such that the

event if it occurs will cause loss or injury to the insured. A comparison of property insurance and personal insurance reveals marked differences in the application of the Anglo-American legal requirement of insurable interest. In property insurance the insurer's promise is by explicit wording, as in fire insurance, or by interpretation, as in marine insurance, a promise to pay the insured his loss or damage and the insured's interest is an upper limit of his claim to indemnity; in life and casualty insurance the insurer promises to pay a fixed sum on the happening of the insured event.

In Anglo-American law a legally enforceable right or duty in relation to the insured object is requisite in property insurance; in life insurance a relation of mere factual expectation of pecuniary loss, such as the insured's well founded expectation of beneficence during the life of the person insured, will suffice. Moreover while an insurable interest in property must exist, by the weight of authority, only when the casualty occurs, an insurable interest in life need exist only when the contract is consummated.

The recognized insurable interests in property fall into three main groups. In the first, a proprietary interest, ranging in extent from that of the sole owner to that of the lienholder or the lessee, is sufficient whether its basis be legal or equitable. In the second, a contract right, expressly made dependent upon the insured event or upon a contingency directly affected by it, is a valid interest [*National Filtering Oil Co. v. Citizens' Insurance Co. of Missouri*, 106 N. Y. 535 (1887)], although the contingent claim of an unsecured creditor against his debtor's property has generally been regarded as too remote for legal recognition. In the third, legal liability to pay for loss or damage caused by the insured event provides an insurable interest in that event. Thus the bailee of goods has an insurable interest in them because of his liability to compensate the owner for damage to them. A fourth class of interests, represented by an adult son's factual expectation of obtaining a gift of certain property from his father, is recognized in a few cases [*Home Insurance Co. v. Mendenhall*, 164 Ill. 458 (1897)] but is generally rejected as too uncertain and remote under the influence of an early dictum by Lord Eldon [*Lucena v. Craufurd*, 2 Bos. & P. N. R. 269 (1806)]. In general it may be said that expected profits and other economic advantages contingent upon the safety of property are insurable if supported by a legally enforceable right.

Both French and German law maintain a clear distinction between life insurance, in which no insurable interest is required, and the various types of indemnity insurance. For the latter a factual expectation of economic loss, even though unsupported by a legal right or duty, is both necessary and sufficient to constitute an insurable interest. Hence a legal right of no economic value, such as the ownership of property mortgaged for far more than its value, is not an insurable interest. The contrast with Anglo-American law is thus complete in theory. The actual divergence is less because legal rights and economic advantages usually coincide. Expected gains are insurable in French and in German law.

In the Anglo-American law of life insurance a legal relation, such as a woman's right to support from her husband, is a sufficient insurable interest; but so is a mere factual expectation of benefit from the prolonged life of the person insured, such as that of a foster child not legally adopted to continued support from the foster parent. The unsecured creditor has long been recognized to have an insurable interest in the life of his debtor on the theory that payment of the debt is directly dependent on the debtor's earning capacity. Recent legislation in New York has extended group life insurance to meet this need [N. Y. Laws, ch. 292, sect. 1 (1929)]. The beneficiary's love and affection for the person whose life is insured have, however, been deemed insufficient in a majority of the states of the United States, partly because the English statute of 1774 (14 Geo. III, c. 48) requires a pecuniary interest.

An adult who procures insurance on his own life may name as beneficiary a person who has no insurable interest. The exercise of an independent choice by the former is regarded as a sufficient prophylactic against wagering by the latter. The growing recognition of this principle in the United States, coupled with the established practise of requiring a signed application for life insurance from the person whose life is to be insured, has restricted the problem of insurable interest to the rare situation in which the beneficiary induces the applicant to apply for a policy upon his life paid for by the beneficiary. The older notion that a continuing insurable interest was necessary as a deterrent to mercenary murder was exploded by a brilliant opinion of Justice Oliver Wendell Holmes upholding an assignment (not contemplated when the policy was issued) of a valid policy to one

having no insurable interest [*Grigsby v. Russell*, 222 U. S. 149 (1911)]. Yet the requirement of insurable interest has not been relaxed in American law to the same extent as in German law and French law, which seek to counteract the sinister tendencies of wagering on death by requiring merely the consent of the person insured to the original issuance and to every subsequent assignment of the policy. American statutes frequently limit the amounts insurable at various ages on the lives of minors, even where a parent is the beneficiary. Similar restrictions are found in English, French and German legislation.

The peculiar obligation of the insured to act in good faith toward the insurer is recognized in all legal systems. The doctrine of concealment requires that the applicant for insurance voluntarily disclose all known facts which would materially affect the insurer's decision to make the contract. At a time when the English common law of commercial bargaining was pervaded by the ethics of the jungle, Lord Mansfield to foster the business of underwriting as an aid to the expansion of British foreign trade laid down this doctrine in an opinion [*Carter v. Boehm*, (1766) 3 Burr. 1905] which was substantially copied in subsequent British legislation (Marine Insurance Act, 1906, sects. 17-19). The nullification of a contract because of innocent non-disclosure of a material fact known to the insured was justified by the inaccessibility to the insurer of information about marine risks and by the practise of having expert brokers familiar with the material factors of the risk to represent the insured in negotiations with the underwriter. English law rigorously applies the same rule to other kinds of insurance [*Horne v. Poland*, (1922) 2 K. B. 364]. American courts have accepted this rule for marine or inland marine risks. Insurance against terrestrial risks is avoidable only if the insured has withheld material facts with intent to defraud. This judge made reform was eloquently defended by the late Chief Justice Taft [*Penn Mutual Life Insurance Co. v. Mechanics' Savings Bank and Trust Co.*, 72 Fed. 413 (1896)] on the ground that the insured is inexpert in estimating risks and that the insurer commonly relies upon independent investigation of the risk.

To Lord Mansfield's influence is also due the English rule that the insured's non-fraudulent misrepresentation of fact, which materially induces the insurer to contract, gives the latter a privilege of avoiding the policy. This doctrine

was accepted in American insurance law, but its range of operation has become restricted. In fire insurance the practise of issuing the policy without a written application from the insured has made the doctrine practically inapplicable. In life insurance the legal effect of innocent misrepresentations by the insured in his application has been diminished by judicial decisions and by legislation. A growing minority of courts hold that the insured should not suffer forfeiture because of honest erroneous opinions about his health, however unqualifiedly expressed. Some statutes prescribe that a non-fraudulent misrepresentation avoids the policy if the fact misrepresented is found by the tribunal to have increased the risk—that is, the probability—of death. Others even restrict the insurer's defense to cases in which the fact misrepresented actually contributed to the death of the insured. The scope and effect of these ineptly worded laws remain yet to be settled.

The codification of insurance law which took place in Germany in 1908 and in France in 1930 has mitigated the harsh consequences of the insured's innocent concealment or non-disclosure. Except in cases of fraud the insurer may not in French law cancel the contract for concealment or misrepresentation discovered after a loss has occurred; the insured suffers only a reduction of his claim in inverse proportion to the premium which would have been charged had the whole truth been told. The German law adopts the view even more favorable to the insured that a fact which did not contribute to the loss or to the extent of the insurer's liability is no ground for defeating the insured's claim except in marine insurance. Cancellation before loss is permitted in French law even when the insured's deception was innocent; in German law, only if the insured was culpable. In the United States a lone New Hampshire statute [Public Laws 1926, ch. 276, sect. 4 (1926)], revising pioneer legislation in this field [*N. H. Laws*, ch. 1662 (1855)], allows cancellation after loss only if the misrepresentation was fraudulent or if the fact misrepresented contributed to the loss. Otherwise recovery is reduced as under the French law, but the method of estimating this reduction remains obscure.

Oral contracts of insurance are valid in German law and, with some statutory exceptions, in English and in American law but not in French law. The universal practise of insurers, however, save in case of temporary coverage is to issue a formal policy. Since this document is drafted by

the insurer with an eye to his own interests, judicial interpretation favors the insured wherever doubt as to its meaning is possible. The marine policy became standardized in archaic language which left judicial interpretation a wide range of flexibility. The British Marine Insurance Act of 1906 virtually codified this uncouth hulk in its present form along with the encrusted deposits of judicial construction. The paucity of American legislation reveals a *laissez faire* attitude toward this esoteric branch of insurance.

The amazing growth in the United States of the popular branches of insurance during the latter half of the nineteenth century was accompanied by increasing complexity and length of the terms of the insurance policy. Liberty of contract bred weasel promises, against which judicial interpretation struggled with only partial success. Under the guidance of astute lawyers the insurers redrafted their contracts so as to circumvent decisions favoring the insured. In the competition among insurers, legally unrestricted and actually severe, rates were more important than the terms of the contract; and the insured's inability to understand the latter tempted the insurers to multiply the contractual restrictions upon their liability. Many of the restrictions were motivated by a genuine and not wholly unfounded distrust of the common man's honesty in dealing with insurance companies. Thus many American insurers sowed the dragon's teeth of legislative reform. The crop is still maturing.

One of the most salutary results of this legislation has been the compulsory standardization of policy forms. Although leading New York fire underwriters long sought uniformity of policy provisions for their own protection in the adjustment of losses involving several companies under different policies, only the legislative threat of a standard policy to be drafted by the superintendent of insurance [N. Y. Laws, ch. 488 (1886)] spurred them to produce the New York standard fire policy, a form still prescribed with minor modifications in the statutes of many other states. In New York this form was superseded in 1918 by a shorter form, prepared under the direction of the National Convention of Insurance Commissioners, which eliminates some of the harsh consequences of technical defaults by the insured. An earlier Massachusetts form drafted by legislators is even more favorable to the insured. Despite these legislative reforms American fire policies are still much more

lengthy than those used in England and seem to have more technical loopholes for the insurer than those in France and Germany. Workmen's compensation policies have frequently been standardized under American legislation. In life, accident and health insurance the legislation merely prescribes and proscribes certain types of clauses.

The problem of adjusting the technical requirements of a successful insurance enterprise to the needs, capacities and ethical notions of the common man is not peculiar to the United States, where, however, for reasons which are not entirely clear it has become more acute than elsewhere. Technical requirements appear as conditions of the insurer's promise to pay. Non-compliance with any one of these conditions relieves the insurer of liability. Some conditions have a more important bearing on the risk than others; some deviations from the required condition are serious, while others are merely technical. The English law of warranty was developed by Lord Mansfield on the assumption that the court should not inquire into the purpose of the expert underwriter in inserting the warranty or into the materiality of the breach. This assumption, not wholly unjustified in respect to the bargained for warranties adapted by marine insurers to each particular risk, led to the doctrine that any breach of the warranty as literally construed precluded recovery by the insured regardless of the materiality of the breach. This strict rule has been steadily adhered to by the English courts [*Dawsons, Ltd. v. Bonnin*, (1922) 2 A. C. 413]. American courts apply it with widely varying degrees of severity.

The extension of this strict doctrine to modern machine made policies poured forth by a central home office and distributed through a myriad of local agents, many of them indifferently trained and only avocationally interested, wrought havoc with honest claims. Attempts to attain an equitable interpretation of the numerous conditional clauses have led to confusion both in judicial decisions and in legislation. Particularly fruitful of litigation are the numerous fire insurance provisions aimed at fraudulent incendiarism by the insured, such as the clause invalidating the insurance if the insured is not sole and unconditional owner or if the insured chattel is mortgaged or if other insurance is procured without written consent of the first insurer. Judicial interpretation of these clauses in accordance with the purpose for which they were inserted has frequently eliminated technical de-

fenses. Some American states have enacted that only a default which is material to the risk will avoid the policy. More drastic legislation in a few states requires the insurer to prove that the breach of condition actually contributed to the loss. The German insurance code excuses the insured's default if he proves that it did not contribute to the loss. The French law of 1930 affords less liberal protection to the insured.

Another embattled safeguard in American law is the limitation upon the local insurance agent's power to bind his company. Either he has no authority whatever to modify the printed forms, as in life insurance, or he has authority to modify only by a written endorsement, as in fire insurance. These restrictions, coupled with the parole evidence rule which excludes proof of contemporaneous conversations not embodied in the written contract, tend to effectuate uniform centralized home office control over multitudes of local agents. Yet the ordinary man accustomed to the looser dealings of local merchants and department stores can scarcely understand why the agent who takes his premium has no power to bind the company by oral statements. The harsh consequences to the insured of this slot machine plan of distributing insurance coverage are mitigated by the twin doctrines of waiver and estoppel. While the American decisions are in hopeless confusion as to the scope and meaning of these doctrines, it may be said that they apply in general where the insurer's agent with knowledge of the insured's default lulls him by soothing speech into a sense of security without properly endorsing the policy. The federal courts rigorously exclude proof of the agent's contemporaneous conversations unless the insured sues in equity to reform the policy. A decided majority of the state courts allow such proof, in a trial by jury, for the purpose of relieving the insured of a breach of condition. Hence the insured's rights will often depend upon whether or not the insurer can seek the beneficent protection of the federal courts. At their best waiver and estoppel impose upon the insurer a duty of serving the individual needs of the insured. At their worst they cloak fraudulent claims or rationalize judicial sympathy and prejudice.

Sympathy and prejudice, particularly of jurors, add to the American insurer's troubles a juridical risk unmatched in England, where judges control juries, or on the continent, where judges alone decide. Had the English statute of 1601 (43 Eliz., c. 12), which sought to take in-

surance litigation from the common law courts by creating a special insurance court, been successful, American law might have inherited a special jurisdiction for insurance cases similar to that of the juryless admiralty courts. As it is, jurors' verdicts against insurance companies reflect the same tendency to effect a redistribution of wealth which is manifested in verdicts against other rich corporations. The introduction into life insurance policies of a clause making the insured's claim legally incontestable after one or two years from date of issuance has proved an unforeseen boon to insurers by opening the doors of the juryless equity court to the timely cancellation of a policy procured by deception.

The growth of social insurance, although more backward in the United States than abroad, has been paralleled by an increasing tendency to make private insurance coverage available for victims of the casualty other than the contracting party. This tendency has been most marked (aside from workmen's compensation insurance) in automobile liability insurance, where statutes which perfect the injured person's claim against the insurer of the automobilist who injured him have been upheld by the Supreme Court on the ground among others that liability insurance tends to make the driver more careless and thus enhances the danger to other persons [*Merchants' Mutual Automobile Liability Insurance Co. v. Smart*, 267 U. S. 126 (1924)]. Quasi-negotiable marine insurance certificates protecting all persons who become interested in shipments of goods have facilitated export trade, and fire insurance obtained by bailees on goods "held in trust or on commission" serve a similar purpose in inland trade. While American and English laws still treat the ordinary fire policy as a "personal" contract which does not follow the transfer of the property, in France and in Germany automatic coverage of the transferee, at least for a brief period, is now the rule. The use of life insurance to protect the widow and children of the breadwinner has been recognized in numerous American statutes which exempt the proceeds of the policy in the hands of the beneficiary from the claims of the insured's creditors, even in case of bankruptcy. This is only another example of the way in which insurance law transcends the bounds of the individual contract. Another tendency away from an individualist economy is seen in the growth of mutual insurance carriers.

Legislative and administrative regulation of insurance enterprises dates from almost the be-

ginning of modern commercial insurance. The Barcelona Code of 1435 prescribed brokerage fees, and a Florentine law of 1523 established official control of rates and of policy forms. Regulation of reserves and investments were introduced by nineteenth century American legislation. Not until the twentieth century did English or continental legislation approach that of the United States in strictness, and today only Germany (law of 1901, with drastic amendments in 1931) exercises a comparable degree of supervision.

Four types of state control have been used. The state may prescribe the initial qualifications of a new enterprise, as in the early special incorporation statutes of Massachusetts. The state may require annual publication of financial statements on the assumption that the insuring public will thus be enabled to choose the more reliable companies. This device was unduly relied upon in early American legislation. The state may establish norms for the subsequent conduct of the enterprise, backed by criminal penalties or the threat of judicial receivership. Finally, without abandoning any of these devices the state may establish a continuous official supervision with summary administrative powers. This last stage has been attained in every state of the United States by investing a single official (the insurance commissioner or superintendent of insurance) with these powers. In Germany and in France advisory committees representative of insurers, insured and actuaries participate in the official control.

In England the attempts of the Privy Council from 1574 to 1576 to regulate marine insurance rates proved abortive. Insurance enterprises as such were not subjected to regulation of their financial arrangements until 1870, when life insurance companies were required to make initial deposits of £20,000 each and to file financial reports annually with the Board of Trade (33 & 34 Vict., c. 61). The same or similar requirements were extended in 1907 and again in 1909 to other types of insurance companies. The Assurance Companies Act of 1909 (9 Edw. VII, c. 49) for the first time brought individual underwriters, such as the members of Lloyd's in London, within the scope of such regulations; yet the beneficent autonomy of those individual underwriters' associations, approved by the Board of Trade, was preserved by exempting their members from requirements other than the deposit of £2000. The vexatious problems of fraternal societies were dealt with more compre-

hensively and effectively by the Friendly Societies Act of 1896 (59 & 60 Vict., c. 25) than by comparable American legislation. The Industrial Assurance Act of 1923 (13 & 14 Geo. V, c. 8) confers summary inquisitorial powers on the industrial insurance commissioner and attains continuous administrative supervision. Thus English legislation better safeguards the interests of the proletarian policyholder than of the well to do. In the United States the converse has generally been true. On the whole regulation in England has been mild.

The American insurance commissioner or superintendent has extensive and flexible powers over the conduct of insurance enterprises. He may refuse to issue or revoke an insurance company's license, and the unlicensed insurer becomes subject to heavy penalties if it continues to do business. The grounds of refusal or revocation are sometimes specifically prescribed by statute; but in other instances a blanket provision is added, such as "whenever in the judgment of the superintendent of insurance it will best promote the interests of the people of this state" [N. Y. Laws, ch. 9 (1913)]. Grounds for the revocation of agents' licenses are more narrowly prescribed. In those few states which authorize the licensing of insurance brokers revocation is usually authorized on the ground of untrustworthiness or incompetence. Another important administrative device is the commissioner's power to demand the privilege of making an extensive examination of the books, securities and affairs of local enterprises, commonly at the expense of the enterprise examined. To ascertain the financial safety of insurance companies he is authorized to evaluate their assets and liabilities and to approve or disapprove their investments. His powers over policy forms are somewhat less discretionary and apply only to a few types of insurance. Only in the exercise of his power to prescribe rates, usually limited to fire and to workmen's compensation insurance, does he ordinarily hold a formal hearing.

Elastic discretion and inadequate procedural safeguards have led to some abuses, less frequently through corruption than through official zeal to stretch the scope of regulation beyond the terms of the statute. Thus the tendency to enforce by unauthorized administrative sanctions the payment of private contract claims against insurers or against brokers is an encroachment on the judicial prerogative of determining the validity of such claims. While judicial remedies against the commissioner are available to check

these and other bureaucratic abuses, they are sparingly invoked by insurance companies because of the resultant unfavorable publicity and official ill will.

It was early held that the regulation of interstate insurance business is beyond the powers of Congress over interstate commerce [Paul v. Virginia, 75 U. S. 168 (1868)]. Hence each state enforces its own legislation as to both domestic and foreign enterprises. The power of the state to exclude arbitrarily an insurance corporation of another state has, however, been denied by the Supreme Court [Fidelity & Deposit Co. of Maryland v. Tafoya, 270 U. S. 426 (1926)]. The burdens imposed on interstate insurers by forty-eight autonomous officials and some ten thousand sections of insurance law are lightened by extralegal influences. Imitation of the legislation of other states, notably of New York, has lessened divergences. The National Convention of Insurance Commissioners, organized in 1870, a gathering of state officials which meets twice yearly, has conducted numerous investigations of their common problems, drafted important uniform legislation and standardized administrative practises, especially in regard to the voluminous annual reports required of insurance companies. By expediting the interstate exchange of official examiners' reports it has decreased the expense to the companies of multiple supervision and relieved the smaller state insurance departments of tasks for which they are inadequately manned.

The constitutional limits of the state's police power over the insurance business are not clearly defined. Since the Supreme Court upheld the regulation of fire insurance rates on the ground that competition was practically ineffective [German Alliance Ins. Co. v. Lewis, 233 U. S. 389 (1914)], the insurance business has been in some measure "affected with a public interest." Although insurance companies are forbidden to discriminate unfairly between applicants for insurance or to give rebates to those whom they choose to insure they are not like public utilities under a legal duty to serve all who apply. No showing of public necessity or convenience is prerequisite to the incorporation or licensing of a new insurance enterprise. Insurance is in the twilight zone of state control.

State supervision of insurance has passed the experimental stage. In the United States its preventive work has well protected the insuring public from commercial enterprises inadequately capitalized or fraudulently managed. Its

constructive work has effectuated important changes which the insurers would not or could not bring about voluntarily. A notable example is the establishment of the compulsory reserve and of the life policyholder's right to a share of the reserve fund, the cash surrender value, through the efforts of Elizur Wright, commissioner of Massachusetts, after the middle of the nineteenth century in 1854-61. Here as in other constructive efforts the state bureaucracy has served less by invention than by selecting its norms from among those professional standards and business mores which are deemed to have the greater social utility.

INSURGENCY, POLITICAL. Rebellion against authority is far from rare. It is attempted in various forms and for various motives and has various consequences. In international law the term insurgency is used to describe an internal political revolt which the withstanding state does not wish to recognize as war and which other states are not ready to recognize as belligerency (see **INSURRECTION**). The consequences are of interest to international lawyers but the situation arises with relative infrequency.

The term insurgency is more often employed in domestic party politics. There have doubtless been insurgents wherever authority has been asserted over groups, but the word was first used to describe those Republicans who in 1909 revolted against the party leadership in the House of Representatives, dethroned Speaker Cannon and reformed the rules of the House.

The 1909 movement was not the first movement of its kind in American party history, for insurgency although not called by that name had raised its head in 1872 and in the 1880's and 1890's.

Dissatisfaction with the first Grant administration, lack of confidence in the leadership of

the Republican party and a desire for a different policy toward the South led to the movement of liberal Republicans in 1872. The leaders of these dissentients were distinguished men—Carl Schurz, Charles Francis Adams, William Cullen Bryant, Lyman Trumbull, Whitelaw Reid—who had outstanding ability and possessed the public confidence. A liberal Republican convention nominated Horace Greeley for the presidency and the nomination was endorsed by the Democrats at their convention in Baltimore. Grant was elected and, since his second administration was no more successful than the first, the liberal Republicans continued their irregularity. After Hayes was nominated most of them became regulars. In 1884 independent Republicans supported Cleveland on the ground that Blaine was an unfit leader. They were called mugwumps, an epithet which had been used to describe the liberal Republicans of 1872 but which did not gain currency until it was used as a name for the influential Republicans—again including Carl Schurz—who bolted their party twelve years later. During Cleveland's administration there were "silver Democrats," and in 1896 "gold Democrats" were unwilling to accept Bryan as the nominee of the party. They put up their own candidate, but he polled only 130,000 votes.

These insurgent movements were connected with presidential nominations and campaigns. The movement of 1909 began on the congressional terrain. Its principal objectives, which were attained in March, 1910, by coalition with the Democrats, were the exclusion of the speaker from membership on the Committee on Rules and the election of the committees by the House instead of their appointment by the speaker. Once these objectives had been attained, the movement in all probability would have had few further immediate results had it not been for the attempt made by President Taft to discipline the insurgents and for the split between President Taft and Roosevelt. The insurgent Republicans were prominent in the Progressive party of 1912, but by 1916 most if not all of them were again regular. Some of them became irregular again when Senator La Follette ran for the presidency on a third party ticket in 1924.

The term insurgency is still used to describe "progressive" Republicans who are out of tune with the regular leadership. In recent years congressional insurgency has largely been confined to the Senate, where its objectives have been chiefly legislative and inquisitorial. The con-

gressional investigations of the Harding and Coolidge administrations were largely brought about with the support of the insurgents. It is interesting to note that the insurgent movement of 1909-10 and recent irregularity in the Senate have been led by representatives and senators from the west. This is natural enough, for the leadership of both American political parties still derives from the older sections of the country. It is to be expected that the newer sections will send to Washington representatives whose opinions and interests are not en rapport with the opinions and interests of the eastern and middle western states.

The Democrats have been spared—or have not been blessed—by an insurgent movement similar to that of 1909. One reason is doubtless the fact that the Democrats are usually in the congressional minority. Insurgency seems to be encouraged when a party has a majority, for then leadership is highly prized—so small a value is placed on a vigorous party opposition in the United States—and tends to bring forth the countervailing tendency of insurgency. It would be accurate to say, however, that dissentient groups in the Democratic party have been just as frequent as dissentient groups in the Republican party; but their identities have been inchoate and their activities have been temporary and not too notorious.

The indigenous character of American party development, with the parties extragovernmental, elaborately organized, under irresponsible leadership and made up of loose federations of state or sectional parties, encourages factionalism. Insurgency can be an avenue to political prominence. A larger percentage of insurgents than of regulars can become known to the country. Irregularity is more interesting than regularity, while it is not unlikely that there is a higher percentage of able men among the revolvers than among the regulars. Unlike politicians on the continent, American insurgents cannot use their irregularity to obtain cabinet posts or the one great prize in American politics, the presidency. American political parties are inclined to select only "safe" men for their highest posts. Publicity, in short, is the principal means and perhaps the chief end of political insurgency in the United States. There is no possibility of influencing the tenure of a government or of persuading a parliament to withdraw its confidence from the executive. A revolt can accomplish little more than to force the regular organization to modify its policy. Or it may add numerical

strength to the minority party so that the majority group becomes a minority. Finally, the price of acquiescence may be greater legislative preferment for the revolters—consideration of measures which they espouse or better places in the committee hierarchy of Congress.

It is interesting to note that representatives and senators who insurge in Congress are infrequently irregular in presidential elections and that their temporary independence rarely means even temporary abandonment of the party label. Since the insurgents are dominant in their local party organizations—for example, Senator La Follette always controlled the Republican party machine in Wisconsin—the only discipline which the national party may attempt is a withdrawal of federal patronage or a threat of exclusion from important congressional committees. These sanctions may be boomerangs, as President Taft discovered. If the party majority is small, the congressional leaders may need insurgent votes to “organize” Congress; or the party leaders may simply conclude that discretion is the better part of valor. In these cases discipline is not attempted.

Complaint is sometimes made that the irregular senators and representatives from smaller states have prominence and power disproportionate to the size and influence of their constituencies. There is little merit in such a suggestion; for an irregular senator sent to Washington by a majority of the votes of a small state may be an effective representative of sizable minority opinions in large states. In Congress the legislative hopes of insurgents or progressives or irregulars are made more easily realizable by the bipartisan character of the bulk of congressional legislation. As is frequently pointed out, few important laws are driven to the statute book by the advocacy of one party in the face of opposition by the other party. Congressional majorities are usually bipartisan and under such circumstances a bloc of representatives or senators, anxious for more progressive measures than the regular majority leaders are willing to sanction, can be extremely powerful.

In Great Britain and on the continent political insurgency is far from unknown, but because of different governmental structures and party organizations it has disclosed different tactics and objectives. In Great Britain revolts against party leadership have had different strategy and objectives. For example, Liberal dissentients known as Adullamites and headed by Robert Lowe and Lord Hugh Grosvenor opposed on

principle Gladstone's Reform Bill in 1866 and were largely responsible for the defeat of his government. In much the same way twenty years later the Irish question created irreconcilable minorities in both the great English parties. But this defection was so extensive and so continued that its participants were not in the same category with the occupants of the cave of Adullam.

A better English illustration is perhaps the Fourth party, which indeed had hardly more than four members. The two ablest were Arthur Balfour and Lord Randolph Churchill. Organized in 1880 after Gladstone had won his Midlothian campaign and when the leadership of the Conservative opposition in the House of Commons might have been more vigorous and effective, the Fourth party made its members far more prominent than they could have been if they had remained regular Conservatives. Partly because Gladstone's temperament made him easy to bait—and the brilliant Fourth party men knew how to do it—they were far more annoying than were the leaders of the official opposition. There was in this insurgency slight divergence on principle. The consciences of Balfour and Lord Randolph were not bothered by what they conceived to be mistaken Conservative doctrine. They wished to make their mark in Parliament quickly; and insurgency was the highly successful method that they employed. All four members of the party were given office in Lord Salisbury's government and their insurgency was at an end.

On the continent, where most cabinets are coalition cabinets and parties are multiple, irregularity is frequently the shortest road to ministerial preferment. This is not to say that doctrinal differences do not exist. Splits in the French Socialist party, for example, proliferated a single organization into several, and in other continental countries the same phenomenon has been responsible for the post-war birth of communist parties. But what may be called insurgency frequently occurs in France because of reasons which to the foreign observer seem purely personal. To the intimately informed the nuances of doctrine may be perceptible, but to the outsider it frequently seems that a group of deputies withdraws from their previous group and organizes their own group solely for the purpose of prominence and profit. Since a French cabinet must pick its members so as to secure the support of a majority of deputies, a newly organized group may be strategically

placed. One or two of its members may receive the accolade of office solely because of their separate organization. Hence revolt against authority can be made a stepping stone for the revolters.

When parties are elaborately organized and under strict discipline, insurgency is a more serious and less promising manoeuvre. If the members of the Fourth party had been less able and less well connected they would have been punished by ostracism. On the other hand, insurgency within a well organized party may continue for a time but may have to result in separation. The difference may be tolerated if it relates to a matter of strategy—for example, as to whether the members of the French Socialist party should participate in forming a bourgeois government—but when the difference is doctrinal cleavage is likely.

Insurgency of course manifests itself in non-political groups: in churches, educational institutions, trade unions and so on. Sometimes it is little more than a matter of personal cleavage. The insurgents desire the positions which the leaders hold. In other cases there are differences of principle. The clash between modernists and fundamentalists is one of doctrine although it may be exacerbated by the clash of personality. In some trade unions—notably the textile unions, whose membership is largely made up of immigrant races—insurgency is communistic. The essence of statesmanship, whether it is political or industrial, is to detect dissentient movements before they become formidable, to scotch them or to put their leaders in office and thus encourage them to become regular. It is the essence of leadership also to remember that while some men are born insurgents and some deliberately seek to be insurgents, some have insurgency thrust upon them.

INSURRECTION. While the term insurrection as used by international lawyers and jurists to refer to a particular legal situation has a reasonably precise meaning, its use by historians, political scientists and sociologists is unfortunately characterized by extreme ambiguity and confusion. It is loosely used along with revolution and rebellion to refer to an armed resistance to government. In general an uprising directed toward a radical modification of the existing political or social order throughout the whole territory of a state is referred to as a revolution, while the word rebellion is more frequently confined to efforts on the part of a portion of a state to throw off the authority of the remainder. Insurrection usually refers to movements smaller in scope and purpose than those described by the other terms. But obvious exceptions come to mind at once. The American Revolution was in reality a rebellion. The insurrection of the Paris Commune of 1871 was an abortive social revolution, while the Great Rebellion in England in the seventeenth century was a temporarily successful revolution. The Whisky Rebellion in the United States and the Sepoy Mutiny in India were both insurrections.

Whether the distinction between types of resistance to government be based upon scope and extent, purposes or methods, no sharp line can be drawn between the three terms. It may be suggested, however, without departing from common usage that the term insurrection should be limited to the initial stages of movements of opposition to government which take the form of armed violence as distinguished from non-violent non-cooperation or passive resistance. Such armed movements may develop into what may better be described as rebellion or revolution, depending upon whether they are directed toward territorial secession or toward the overthrow of a government throughout a state. The use of the more general terms is justified, however, only when the movement attains sufficient magnitude to require the use of a substantial portion of the armed forces of the established government for its liquidation and when it has definite political objectives beyond mere negative resistance to constituted authority. In this

sense an insurrection may be thought of as an incipient rebellion or revolution still localized and limited to securing modifications of governmental policy or personnel and not as yet a serious threat to the state or the government in power.

Considered as a phenomenon of social and political dynamics insurrection involves the use of armed force against the established government in order to achieve public purposes which cannot in the opinion of the insurgents be achieved by pacific means. Motives may be private but insurgents almost always tend to rationalize them in terms of public good, and the ensuing struggle is for control of the machinery of the state. Pacific means of attaining political objectives are adequate so long as the contestants for public office and political power envisage their particular interests as phases of the general interest or are at least prepared to subordinate them to the prevalent conception of the general good as represented by those in authority. When this is no longer the case, acquiescence is no longer forthcoming and armed action is likely if circumstances offer hope of success. In other words, the "constitutional consensus," which normally furnishes the frame of reference within which the political process continues peaceably, breaks down under the tensions between the hostile and irreconcilable groups into which the body politic has become divided. Discussion, bargaining and compromise are then replaced by coercive violence in the clash of rival wills to power. Whether the ensuing insurrection develops into factional warfare, secession, political overturn or social revolution depends upon the lines of cleavage between the conflicting forces. In every case a resort to armed resistance emerges out of a politico-social situation in which irreconcilable interests and programs are adhered to in such uncompromising fashion that the risks of an open trial of strength seem less dangerous to the contestants than continued acquiescence in a situation which is regarded as intolerable.

The effectiveness of insurrection as a political weapon can scarcely be measured in abstract terms, since the variables in each instance are too numerous to admit of prediction and insurrectionary movements are frequently carried forward by their own momentum into rebellion or revolution. Governments threatened by insurrection usually resort to armed repression, the success of which obviously depends upon the fortunes of war, the numbers and organization of the insurgents and the attitude of groups

hitherto neutral. Concessions may sometimes be made to forestall armed action and to weaken the ranks of the rebels. If an outbreak occurs and is put down, the treatment meted out to the defeated groups will depend upon the attitude adopted by the government in power toward their purposes and their capacity for creating future disturbances. Where the line of force is drawn between geographical sections or parties or factions, with basic economic and social interests not involved, the defeated insurrectionists are likely to receive only mild punishment and may even secure a complete or partial redress of grievances. Where the struggle is a true class war, repression is likely to be savage and merciless, as in the Red and White terrors of post-war Europe. The importance attached by the contestants to the interests at stake conditions the attitudes of the contending groups toward each other.

In international law the concept of insurgency has recently been accepted as a basis for defining the legal rights and obligations of states in public disorders more serious than mob violence and less serious than true civil war. Outside states may legitimately take cognizance of the existence of a condition of insurgency when their interests are affected. In 1895 President Cleveland recognized the existence of a state of insurgency in Cuba. Similar action has frequently been taken with regard to civil disturbances in other Latin American states. Such action confers no special rights upon the insurgents, but merely recognizes a state of fact and warns nationals of the state taking the action that the situation warrants more vigorous enforcement of local neutrality laws. The question of whether the state in which the disturbance is taking place is responsible for injuries to aliens resulting from insurgency has usually been answered in the negative when due diligence has been observed in the protection of foreign lives and property and the injuries result from *force majeure* which the *de jure* government, despite its best efforts, has been unable to suppress. Occasionally, however, the United States and some European powers have attempted to enforce liability upon weaker states in which insurrections are chronic. Interference by outside states on behalf of the insurgents is contrary to the principles of international law. The act passed by the United States Congress in 1912 authorizing the president to prohibit the export of arms or munitions of war to American countries in which "conditions of domestic violence exist" has under the provision giving

the president power to prescribe limitations and exceptions to the operation of the law been frequently applied to hamper insurgents in Latin American countries. The Sixth International Conference of American States in 1928 adopted a convention prohibiting all traffic in arms with insurgents. If an insurrection leads to persistent and widespread hostilities, outside states may recognize the belligerency of the insurgents, as did Great Britain and other European states in the American Civil War. In this case the local state is relieved of all responsibility for insurgent acts and the usual principles of the international law of war and neutrality apply.

INTEGRATION, INDUSTRIAL. *See* COMBINATIONS, INDUSTRIAL.

INTELLECTUALS are persons possessing knowledge or in a narrower sense those whose judgment, based on reflection and knowledge, derives less directly and exclusively from sensory perception than in the case of non-intellectuals. Although moral or aesthetic development is often associated with intellectualism, these qualities stem from other roots and are not indispensable components. While intellectuality is not, as Schelling and others have held, necessarily productive, those who have merely accumulated knowledge are not true intellectuals. The scholar must possess priestly qualities and fulfil priestly functions, including political activity. His knowledge, as Fichte says, "should be truly applied for society's use; he should get people to feel their true needs and acquaint them with the means of their satisfaction" (*Werke*, vol. i, Leipsic 1908,

p. 258). While the most typical intellectuals are academicians or instructors in schools of higher learning, it would be wrong to define intellectuals in terms of academic examinations; while they are necessarily educated, the education they possess may vary widely in quantity and type from case to case. The "half" educated, the "eternal student," even the self-educated man—all are intellectuals in so far as they assimilate the materials of knowledge and employ them in mental labor, in so far as they are vocationally concerned with things of the mind.

Intellectuals play a special role in social life. In general they tend to revolt against the existing order wherever it hinders their freedom of intellectual activity. Their demand for freedom of teaching, freedom of study, university autonomy and freedom of student activities has played a prominent role in the development of movements of revolt in Europe and is beginning to be of some importance in the United States. Furthermore since their intellectual pursuits bring them into contact with theories and information not available to others, they often come to regard the social order in which they find themselves as anachronistic with reference to ideas and institutions developed elsewhere or at other periods. Hence they acquire an intellectual motive for urging change; this assumes a patriotic coloration when they feel that the change they advocate is a national need. These attitudes were typically expressed by the Russian Decembrists and the westernists in general in their struggle against czarism. A characteristic influence over general developments was exercised by the intelligentsia in eighteenth century France. The best representatives of the bourgeois intelligentsia from Rousseau to Voltaire were absorbed in "philosophy" rather than in economics or politics. Devoted to generalizations and the elaboration of logical constructs, they came more and more to champion "pure principles." Thus largely without conscious intent they served the French Revolution, seriously weakening the political resistance of the ruling classes by undermining their confidence in the good of their cause. The revolution itself was swept by intellectualism, especially that naïve optimistic belief which the Jacobins communicated to the masses—that since evil in men was the effect of bad state institutions and their ideologies, a change in the form of the state and the work of the guillotine would restore "natural good" to the hearts of the survivors.

The thesis that intellectuals champion revolu-

tionary ideas must, however, be taken with a grain of salt. In most historical cases only a section of intellectuals has been involved, as, for example, an age group or a professional group. While the French *Jeunesse des Écoles* was radical, there was no corresponding solidarity among the professors. German literary men in the first half of the nineteenth century opposed government institutions and state power and were more patriotic, more social minded and more radical than the more or less well to do official professors and bureaucracy with the same intellectual training. In Paris in 1830 and 1848 and in Vienna in 1848 university students formed revolutionary legions, and the German *Burschenschaft* and the Russian students have also been more or less revolutionary; but it is beyond historical proof and contrary to knowledge of the behavior of comparable groups to maintain that this was true of all the students. While in France the political and historical sciences, whose most prominent representative was Louis Blanc, served the Revolution of 1848, Proudhon correctly maintained that the literary intellectuals handicapped it by diverting the passions of the masses into romantic and erotic channels. In England the participation of university trained men in socialist politics has never been extensive, except perhaps in the Chartist movement and in the Fabian Society, a study group rather than a political party. This has been a consequence of the fact that in England politics as a profession was and in part still is the privilege of people of means (election contests are extremely expensive) who have achieved a career or who because of their aristocratic birth need none. In the United States intellectuals, who are usually not well off economically and who are socially overshadowed by business men and without *esprit de corps*, are largely dominated by utilitarian values and only a limited number are to be found in the leadership of unions or radical political parties.

The theory that the intelligentsia has an immanently revolutionary character is then not in accord with the facts. Differing among themselves basically in origin, character, training and theory, intellectuals are the officers and subalterns of all arms and of all armies. In the politics of any period the parties of revolution, of continuity and of reaction have all been in their hands, and thus in a sense their efforts have negated each other.

Intellectuals have played important roles in stimulating national consciousness, the basis of

their attitude being some form of the idea that the nation has a mission. This mission can be accomplished only with the aid of an extensive intellectual staff of mythologists, archaeologists, poets and the like, although the result of their work corresponds somewhat with an existing popular feeling. The late Middle Ages, the Renaissance and the Reformation were to some extent colored by the nationalism of intellectuals whose professional interests as a consequence of the rise of the national languages for court and literary use tended away from the universalism of Latin and the papacy. The struggle against ultramontanist had not only a religious, social and politico-economic basis but also a basis in the desire of intellectuals to strengthen their position in their respective countries.

During the nineteenth century in Europe intellectuals cultivated the nationalist idea, kept it alive during difficult times and led it to victory over all obstacles. Today students are among the foremost leaders of nationalist movements in Asia and Africa. While crude mass nationalist reaction against foreign rule has always played an important role, the struggle of nationalist political movements for power has had to await intellectual leaders to shape ideas, to spread them among ever widening masses and to stimulate popular response. It may be said that without students, professors, journalists and writers no modern national state could have come into being. More recent language conflicts in Europe have had important roots in the fact that considerable pecuniary interests of publishers, editors, authors and journalists are bound up with the maintenance and advance of any national speech. These persons are natural defenders of the language and its literary monuments with which they happen to be linked emotionally as well as professionally. In countries of several nationalities, as, for example, the Austrian monarchy, there arose out of such circumstances national conflicts over schools, universities and government offices. Intellectuals had to fight for their nationality as for life, for an Italian savant without an Italian university or a Czech poet without a popular Czech school system had little significance. In some situations nationalist intellectuals, hampered by cross currents of economic interests in their efforts to organize broad masses of workers or peasants on the basis of a national culture and to fight a nationalist struggle, come to advocate a socialist society as the only one which can solve the nationalist problem.

The World War, at least in its literary expressions a struggle among national cultures, mobilized intellectuals by placing upon them the burden of lower and intermediate army leadership and by using them to elaborate a rationale for the war. In this task strong emotion was achieved by intellectuals at the expense of pure science. They turned out many literary nationalist manifestoes, such as *Es ist nicht wahr* (1914), in which German scientists proved themselves thoroughly uncritical and platitudinous, and the *Manifeste du parti de l'intelligence* (1919), issued by fifty-seven French intellectuals, chiefly litterateurs, advocating a national policy of force. The Italian official professorial staffs in 1915 justified by irredentist ideals Italian participation in the World War.

In many central and east European countries, especially since the war, growing numbers of intellectuals and students participate in anti-semitic movements. While the basis of antisemitism has often been ethnical and sentimental, the fact that a disproportionate number of Jews are economically able to acquire advanced education and to pursue learned professions has played a major role in creating these movements and in spreading them through academic circles. Jews are less numerous and more assimilated in England, Italy, the smaller countries of northern and central Europe and France; these countries have been relatively free from this attitude despite the fact that some faculties (business law, mathematics, economics) are largely manned by Jews. Although academic antisemitism is without political form in the United States it is not uncommon, and most faculties of non-professional schools, especially in the more important universities, are practically closed to Jews. The *numerus clausus* for Jewish students applied openly in some central and east European universities is achieved in many American institutions by administrative action.

The greatest contribution of intellectualism to a practical movement is Marxism. By transferring socialism from the utopian to the scientific level of thought and by demonstrating the existence of an objective, economically inevitable trend toward socialism it intellectualized the modern labor movement, endowing proletarian interests with the ethical aspects of a universal cultural movement, and made it conscious of a "scientific function"—bearing the germ of a new society.

This achievement, which has had such boundless political consequences, was largely the work

of bourgeois intellectuals; indeed it may be stated as a historical law that class movements are led by members of the classes against which they are aimed. Marx correctly said in the *Communist Manifesto* that it was the tragic fate of the bourgeoisie to be the teacher of its economic and social archenemy, because it is compelled in its constant battles ("at first with the aristocracy; later on, with those portions of the bourgeoisie itself, whose interests have become antagonistic to the progress of industry: at all times, with the bourgeoisie of foreign countries") "to appeal to the proletariat, to ask for its help, and thus, to drag it into the political arena," supplying it with a weapon, in the form of education, which is destined to be turned against the teacher. In addition the bourgeoisie becomes the fencing master of the proletariat when as a result of constant interclass contact members of the bourgeoisie, especially many intellectuals, are detached and use their knowledge and spirit to inspire the working masses to struggle against existing conditions.

Intellectual socialists are of the following main types: ethicists, armed with social conscience; scientists, convinced of the necessity for or the practicability of socialism; demagogues; quacks, selling confused ideological merchandise; men of the Coriolanus type, who desire revenge for personal misfortune, including in a depersonalized, class sense the so-called intellectual proletariat, the declassed; and satiated rich men, philanthropists or *grands seigneurs*. These types fall into two principal categories: "missionaries" and "interested parties." There are of course innumerable mixed types. Sometimes special groups of intellectuals tend by virtue of their particular experiences to drift toward socialism more rapidly or more generally than the whole body of their fellows. For example, the percentage of intellectual Jews in socialist ranks is relatively large. This fact may be explained by the analytical and critical qualities which the social experience of the Diaspora has bred in the Jewish mind. In pre-war central and eastern Europe furthermore social oppression, especially as expressed in the *numerus clausus* in the universities, when it did not divert the ablest Jews into business caused them to suffer keenly at the hands of prejudiced authority. In addition many were forced to study abroad, an experience which accentuated the comparative looseness of the Jew's connection with the traditions of the peoples among whom he dwelt and laid an emotional basis for internationalist ideology. Other

groups of intellectuals who have suffered from similar discriminations have shown comparable trends to radicalism of varying degrees; such are aliens, religious dissidents and, latterly in the United States, Negroes. In the case of the Jewish intelligentsia their international relations and relationships and frequently an element of Hebraic Messianism contribute to their radicalization.

Ethically the alliance of bourgeois and talented intellectuals with socialist parties signifies a capacity for entering into the alien fate of the masses and adapting their personal, individual fates to it. While the worker may be driven to socialism merely as an instinctive reaction to his class position, the intellectual reacts in terms of distress involving his intellectual life. He acts under ethical or intellectual constraint, except in those cases where he is instinctively or consciously seeking to use the proletariat as the raw material for a personal political adventure.

As a matter of fact intellectuals are in some ways untrustworthy as leaders of political parties of any character. By their very nature they are often led, especially in parliamentary struggles, to an attitude which tends to blur natural social antagonisms and to hamper the play of class forces. For example, there has developed among parliamentarians in England an atmosphere of sport, "fair play" and friendly agreements among opposing politicians, all of whom are "members of this club"; and in France despite the severity of election and parliamentary struggles an attitude called camaraderie, which combines esprit de corps with an attitude of mutual responsibility, binding deputies of the most diverse parties closer to each other than a deputy is bound to a rank and file member of his own party.

Disgusted by the behavior of their own class and its individual members, intellectuals first tend to have utopian illusions concerning the character of the proletariat; and their subsequent discovery that workers are also human beings sometimes makes them cynical. The purer their intentions and the higher their ideals, the sooner they lose courage in the face of mass cowardice, brutality or egoism. Especially those seeking revenge are led to open or veiled desertion of their ideals by each outstanding success of their policies. They endeavor to lead the masses along paths which lie close to their personal interests and, when the masses are unwilling to follow, sever connections to seek a career upon the basis of the notoriety achieved through them. Again, radical intellectuals tend toward impossibilism;

through favorable circumstances they may lead a movement to a victory which they ruin through excesses and undue severity. More often, becoming dogmatic and pedantic, they ride a movement to death for the sake of "immortal" principles. This tendency toward extremism arises also from the nature of mental work, which can be easily dissociated from hard reality, from the intellectual's experience in the transvaluation of all values and from the vehemence of emotions and convictions, newly released in fighting his former class. Regarded as apostates, deserters and fanatics intellectuals are most hated in the milieu of their birth and hence tend to set up rigid principles which justify their conduct. Moreover the intellectual who engages in social conflict frequently serves a movement poorly or even deserts it because of his dislike of so-called detailed work.

The attitude of the working masses toward the intellectuals who serve them as leaders has its own mode of change. When a movement is still naïve and inchoate, the intellectual who offers his services appears as a savior and as such worthy of confidence and admiration. Even when the supply of intellectual leaders has increased and new, "really proletarian" leaders have begun to develop from the workers' ranks, the intellectual is indispensable because of the increasing complexity of the problems of the party and auxiliary organizations, the broadening of political aims and the invasion of new arenas of struggle, such as parliament. Now, however, the moral position of intellectuals becomes less unassailable; they are accused of job hunting and careerism and are felt to be a foreign body. Furthermore their struggles and intrigues among themselves compromise them in the eyes of the masses. It would, however, be false to assume that leaders drawn from the ranks of the proletariat manifest greater political dependability than those coming from the educated bourgeoisie; the process of becoming middle class is rapid among both labor leaders and the upper strata of the workers, and these too may desert the cause. Nevertheless, labor leaders of proletarian origin tend to discipline severely, to displace and even to mistreat colleagues of upper class origin from a sort of feeling of class struggle. Some intellectuals have tried to win greater confidence from the masses by sacrificing their forms of life to their principles on the theory that words are less effective as propaganda than the silent example of daily life. The ideal of self-denial incidentally involves a heroic postulate

laid down by Bakunin: immediate disappearance or suicide of the leaders after the success of the revolution in order to prevent the rise of a new ruling class in their persons.

While educational categories can be defined only in terms of examinations and diplomas and have no economic significance, Karl Renner's characterization of intellectuals as "those beyond economics" is misleading. Neither those in the liberal professions nor those drawing state salaries are free from the effects of the business cycle in respect to real or money income. Nor are clear divisions along social and economic lines absent among intellectuals. For example, in England students of the old, aristocratic universities of Oxford and Cambridge rank socially above those of the new and more plebeian universities of Manchester and London, and university graduates tend to fall into the middle or the upper middle class according to the amount and type of their training and economic success attained in their professions. Such facts as well as the geographical dispersion of intellectuals make it hard to organize them.

The social status of student bodies is conditioned among other things by the fact that for several years, during which their contemporaries as laborers, merchants and managers of industry produce and earn, they as students only consume and that they enjoy a far reaching qualitative as well as a quantitative autonomy of work known as academic freedom. Thus the university period is a sort of capital investment of time and money, and the very fact of this investment proves that students—aside from scholarship holders or stipendiaries—come from a possessing class. The few exceptions are candidates for entrance to the bourgeoisie, the university acting as a bridge from a lower to a higher stratum of society.

While there is thus a definite logical and empirical connection between property and education, it cannot be said that each class has a fixed amount of education as an immanent peculiarity or necessary cultural attribute. With the exception of the old English universities the student body does not belong *ipso facto* to the bourgeoisie, and intellectuals must not be confused with the bourgeoisie. In eighteenth century France intellectualism was a transition to the *noblesse de robe*; there was then a sharp distinction between manufacturers or merchants and bourgeois intellectuals as subclasses.

Intellectuals in the lower income groups are termed the intellectual proletariat, a phenomenon

which arises as a consequence of an overabundance of persons offering their knowledge in the market. Always a pathological condition, it is caused by an intellectual overestimation of formal education in general; by sudden stoppage in the consumption of intellectual commodities due to general impoverishment; by industrial backwardness which forces youth into the civil service or a liberal profession, both of which are unprofitable because overrun; and to a small extent by personal negligence and foolishness resulting in ruined careers. Intellectuals who do not find a satisfactory place in the social order are retrospectively *déclassés*: they have been lost to their class of origin (birth); and prospectively *spostati* (dislodged): they have not proved their ability to win good jobs. While it is obvious that the size of the intellectual proletariat is related to the rapidity of social change, the intellectual proletariat does not consist merely of unsuccessful members of the upper classes. It also includes the sons of small manufacturers and artisans, who seriously menaced by large scale industry turn to an intellectual profession and endeavor to obtain a place at the government trough. From the standpoint of the political state there are two main groups of intellectuals: those who have obtained such places and those who have unsuccessfully tried to do so. The first, considered the most loyal of citizens, are always ready because of class egotism and personal selfishness to defend the state which feeds them, no matter what questions are at stake. The others are sworn enemies of government policies, eternally restless spirits which lead the bourgeois opposition and even revolutionary proletarian parties. The number of intellectual proletarians fluctuates widely; but although the state from time to time is compelled to transform thousands of dangerous opponents into active protectors and clients by making them officials, in general the tendency of government officialdom is to grow more slowly than would satisfy middle class elements. Having, however, some expectation of socio-economic advance the intellectual proletariat constitutes a transition class and reflects its characteristics. When this element is impatient or loses hope of improvement it may be absorbed by the lower classes. Poor persons of education become consciously antagonistic to the educated well to do. They furnish the yeast for social revolutions and champion the masses in the class struggle, which in part becomes a struggle for power of two economically differentiated educated classes.

Estimates of the social value of intellectuals

differ widely. Plato, for example, characterized the ideal republic as one in which philosophers would be kings and kings philosophers. Most intellectuals continued to cherish such a view of their kind: after the Napoleonic era the intelligentsia proposed a prominent role for itself, Saint-Simon's doctrine of the producer, for example, calling for a supreme council of scientists to direct economic life; and today intellectuals in many countries insist on their peculiar ability to govern reasonably, fairly and efficiently. The nineteenth century was profoundly influenced by the bourgeois intelligentsia and valued it highly. Early in the twentieth century some intellectuals began an intense spiritual self-criticism, a trend which is still going on and which has found in France its richest expression. Today some writers try to base upon the well known fact that both workers and employers entrust the political advocacy of their interests to intellectuals a theory that the intellectual fulfils a special function of social initiative, creativeness and leadership.

Some Marxists hold that the intelligentsia can maintain its intellectual power and freedom and properly fulfil its creative function only by affiliation with the working class. This view has some support in the fact that while the possession of education, as of riches, the power to command services and exclusiveness, is a hallmark of the bourgeoisie, intellectuals are bourgeois merely through the possession of education, and that while mental work is considered by the bourgeoisie to be more honorable than manual labor—when it is more profitable—to do no work at all and to live on one's income is considered most honorable of all.

In the syndicalism of the Sorel school the function of the intelligentsia shrinks from that of teacher to that of pupil. At the French socialist convention of Toulouse in 1908 Lagardelle defined the intellectual's task not as teaching the proletariat but only as interpreting the proletariat's experiences, using its data and employing its new principles for general cultural work. In any case this function of interpreting the experience which has been accumulated by the proletariat would presuppose the highest degree of intellectualism.

On the other hand, some thinkers have branded the political function of intellectuals as uncreative and sterile and, in so far as it serves the masses, pernicious and intrinsically false. Édouard Berth, Sorel's disciple, complains bit-

terly that producers entrust the championing of their interests to intellectuals who enthralled by demagoguery and without economic interests sell themselves like harlots to all parties for money and kind words, while at bottom they are unable to serve any.

Maurras places before intellectuals two alternatives: money (capitalism) or blood (tradition). He argues that since under the hegemony of finance adaptability to temporary requirements is valued rather than objectivity, the intellect is degraded through loss of independence. Hence the intelligentsia is powerless in a parliamentary democracy, while in a more authoritarian regime, where a caste principle of some sort rather than the principle of wealth would be the element of continuity, it would regain its proper importance. The materials of education and tradition must be taken from the masses, who waste them, so they may again acquire purity and fineness; and intellectualism must be removed from politics. Others, whose values are similar, believe they may conclude from the protest against democracy and the aristocratic tendencies manifest at the beginning of the Third Republic by such brilliant French minds as Renan, Taine and Fustel de Coulanges that the intelligentsia retains the character of an élite. Some intellectuals now ridicule the nineteenth century as the epoch of stupidity, decry efforts to "rationalize the unrationalizable" and oppose to Rabelais' "divine skepticism" the apparent objectivity of Auguste Comte. Others protest against the nationalization and politicization of literary men and scientists, movements which have progressed greatly since 1800; and perhaps Benda is right in attributing this development to the greater intrusion of the state into the life of its subjects. It is of course true that intellectualism is not "purely scientific" in spirit and "universal" in passion but actively champions states, classes and fatherlands. For good or for evil the scientist is no longer "exempt from civic duties"—he is a taxpayer and must do military service; more important, he has been conquered by the "fact," the concrete, and has adapted the world of his ideas to it. But thinkers who protest against this condition tend to emphasize the subjective aspect of intellectualism and to neglect the objective significance of a non-universal, non-scientific nature which characterizes much of the so-called universal and purely scientific intellectual work. In any case no very clear prescription for avoiding political service in its broadest sense has been given by these critics.

In some countries the prevailing trend even of the state is anti-intellectual. Although the Soviet state was partly the creation of intellectuals, today intellectuality in the U. S. S. R. is subordinated to the needs of the state and to a considerable extent "Americanized"; that is, spurred on to performances of maximum energy, particularly in the task of increasing production. In Fascist Italy intellectualism is subordinated to the strongly centralized concept of the state, the military origin of Fascism and its social discipline. At the same time corporationism has given a strong impulse to juristic, technical and some economic studies. In the more or less democratic countries intellectualism although largely demoralized still continues to play its old political role.

Finally, it may be said that while education is undoubtedly power, only a minimum of intellectuality is needed for the acquisition and exercise of political power for any length of time; such factors as energy, self-confidence and understanding of men are of far greater moment. The influence of the intelligentsia upon the mass remains superficial; it can unleash political movements which profoundly change the social structure, but only when aided by objective factors.

INTELLIGENCE. See MENTAL TESTS.

INTENT, CRIMINAL. The modern notion of responsibility in both civil and criminal law seems to involve a mental element. But if in the civil law it is more readily recognized that liability may exist without fault, a criminal act is scarcely conceivable unless deliberately committed by the guilty person. It thus appears almost axiomatic in the modern criminal law that two elements are necessary to constitute a crime: first, an injury; and, second, an intention to cause it.

Nevertheless, the history of the doctrine of criminal intent shows plainly that it is an element that has usually been rendered largely illusory. In many circumstances there may be enormous practical difficulties in distinguishing intent from negligence, and even an accident may appear to be negligence. The legal and popular conceptions of intent do not always coincide. In popular speech physical act, intention and motive are not as sharply differentiated as they usually are in law. In legal contemplation the requirement of intent is met not by the willing of the mere physical act but by the accomplishment of the constitutive elements of a crime. Even when the rules for determining criminal intent have been settled, it is far from an easy matter to apply them. The proof can be had only from external circumstances, a factor which leads either to the relaxation of the rules themselves or to the indulgence of presumptions. Fundamentally a great part of the confusion has been due to the failure to accept all the logical consequences of the requirement of guilt as the basis of punishment. Old notions have persisted.

For historically the necessity for the existence of any mental element is the late requirement. The right of satisfaction recognized by early law is an undifferentiated claim which may in modern terminology be based on tort, crime or a breach of contract; but whatever the basis of liability it attaches to purely external consequences. Since the right of satisfaction is a right to reparation, the question of the wrongdoer's intent is considered irrelevant.

Still the idea appears fairly early that some difference must be made between injuries caused deliberately and those caused involuntarily. In the Pentateuchal legislation (*Numbers* xv: 27-28) a thoroughgoing distinction was made between "ignorant" and "presumptuous" wrongs because in theocratic society sins and crimes are similarly regarded. In Plato's *Laws* voluntary and involuntary injuries are systematically distinguished, and the latter are more severely punished than the former; but Plato is aware that the distinction is something of a paradox and by no means generally adopted. In Hellenistic times various philosophic sects, notably the stoics, introduced moral concepts into legislation and thereby made it necessary to distinguish between the harmful result and the evil will. Punishment was confined as far as possible to the latter: thus Cicero could say that it is an implied rule of mankind (*tacita lex est humanitatis*) to punish not the event but the *consilium* (*Pro Tullio*, 22, 51).

This conception was adopted more and more fully in the mature Roman law. It had always played a larger part in the Roman law than in other ancient systems: the qualification *sciens dolo malo*, "wittingly and willfully," is found in early documents and the supposed sacral law of Numa uses the expression *dolo sciens*. The term *dolus malus* in its abbreviated form *dolus* became in popular and later in technical speech the embodiment of the concept of wrongful intent. While public punishment was permissible only if *dolus* was present, *culpa*, or negligence, sufficed for the *delicta privata*. It is disputed whether in the imperial period after the reign of Hadrian *culpa* was not sufficient in the case of such heinous crimes as murder and arson.

A criminal theory had to be recreated for western Europe during the Middle Ages. The concept of law of the Germanic tribes consisted almost entirely of more or less elaborate tariffs of compensation for injuries. Practically no account was taken of intent or of wrongful

purpose. The liability for consequences was indeed recognized in a maxim: *Qui inscienter peccat, scienter emendat*. But contact with the Roman law and especially the canon law—the developed Christian theology went the full distance of considering only the wicked will as really punishable and the harm done as immaterial—forced men once more to pay attention to the subjective condition of the wrongdoer. The result was, nevertheless, merely a compromise.

The Roman *dolus* received only lip service. The canon law held that *versanti in re illicita imputantur omnia quae sequuntur ex delicto*, which implied no relation of will between the act and its consequences; the mere fact that the offender was engaged in evil sufficed. The ruling doctrine of the Italians, who were especially important in the elaboration of the general doctrines of the criminal law, was that the accused was responsible for all the consequences of an intentional deed which according to an objective standard must necessarily or probably follow from it. From such sources emerged the *dolus indirectus* of Carpzov, which dominated criminal theory almost into the nineteenth century. In its essence *dolus indirectus* is the assertion that all the foreseeable but not necessarily foreseen consequences of a criminal act are to be regarded as willed. *Dolus indirectus* thus represented merely a modification of the idea of *versari in re illicita*.

The necessity for the existence of intent in English criminal law has been expressed in the maxim of *mens rea*. The old Germanic rule of criminal responsibility is found in the *Leges Henrici* of the twelfth century; in this same code, however, in what Liebermann called a "shrieking contradiction" there is a phrase unintelligently filched and corrupted from the *Decretum* of Gratian: *reum non facit nisi mens rea*. This is a sentence from the sermons of St. Augustine referring to perjury, and it is doubtful whether in that passage *reus* had yet acquired its mediaeval meaning of guilty. The maxim is not heard of again until it is cited by Sir Edward Coke in his *Institutes* (3, 6) with the addition of *actus*, and from Coke the requirement of a *mens rea* has been accepted in Anglo-American law.

The difficulties involved began to show themselves as soon as proof of a *mens rea* as an element distinct and separable from the unlawful act was deemed necessary. Such distinct proof was usually unobtainable and recourse in

general was had to presumptions and inferences from the fact that an unlawful act had been committed. The denial of a *mens rea* required the averment of some specific defense, such as accident, incapacity or the like. It is small wonder that Sir James Fitzjames Stephen was ready to declare the phrase *mens rea* to be an entirely meaningless one.

When the source of the maxim is remembered, it would be natural enough to imply that only the "guilty intention" was punishable, but this was never seriously accepted in English law. The proposition *voluntas reputatur pro facto*, "the will is taken for the deed," was voiced in connection with the crime of treason, since the mere "compassing the king's death" was in itself treason. But even here as in conspiracy an overt act of some sort—if only writing the plan out on paper—was in fact required, and the few cases that went further were not considered authoritative.

Indeed English law has gone almost to the opposite extreme of maintaining the old responsibility for consequences. It presumes every adult to intend the natural consequences of his acts. The *mens rea* is present at least theoretically when a criminal act is committed in the course of the performance of a "wrongful" action. This may be not only an act that is a mere civil tort but an act that is a breach of the accepted rules of morality. Such was the opinion of many of the judges in *Reg. v. Prince* [(1875) L. R. 2 C.C.R. 154]. It is true, however, that some crimes require a "special *mens rea*": they are those that must be committed with "malice aforethought," "knowingly," "negligently," "fraudulently." But the effect in such cases is merely to change the burden of proof: the crown must prove the ordinary *mens rea* by further evidence than the mere inference from the *actus reus*. It must be remembered also that "malice" in English law is not equivalent to intent but includes also forms of evil purpose, design or motive. Thus while the terms *dolus indirectus* and *versari in re illicita* are not current English law, the ideas they represent are present perhaps in their most extreme forms.

The American law is much the same as the English, with one most important difference: the *mens rea* is not so readily constituted from any wrongful act. Many courts have held that an act merely *malum prohibitum* will not suffice. Offenses requiring special intent also constitute the exceptions to responsibility for indirect

intention. With respect to at least crimes of homicide (*q.v.*) American law, which has divided murder and manslaughter into degrees, is generally more rigorous than English law in insisting on direct intention. This is indeed a great difference, because crimes of homicide most frequently result in fortuitous consequences, and the most important aspect of the struggle to limit the scope of intention has everywhere been in connection with such crimes, a struggle that has succeeded in most European countries even where *dolus indirectus* is still otherwise recognized.

This is now the case, however, in a decreasing number of continental countries: the most important exception at present perhaps is France. The change has been brought about chiefly through the influence of German criminal law theorists. The campaign against *dolus indirectus* began with Leyser, Böhmer and Nettelbladt toward the end of the eighteenth century. Decisive for the subsequent development was Feuerbach's theory of the psychological compulsion of the criminal law, which led inevitably to the result that only conscious violations of express prohibitions could be punishable. The final result has been that German penal science and the German courts have abandoned *dolus indirectus* with all its associated ideas. Nevertheless, this again has not meant the complete triumph of direct intention. For in place of *dolus indirectus* there has arisen the modern doctrine of *dolus eventualis*, which has come more and more to be accepted in European doctrine and drafts of penal codes.

It is impossible to supply a generally applicable definition of eventual intention, for the reason that the doctrine is not everywhere held in precisely the same terms. In its essence, however, it consists of two requirements. In the first place, the consequences which result from an act must be actually not merely putatively foreseen. In the second place, the person who acts must have taken a certain intellectual or emotional attitude toward these consequences. It is with respect to this necessary attitude that opinions differ. The celebrated so-called Frank formula is based upon the hypothesis that the person who acts would not have been restrained from his deed even if he had come to the conclusion that consequences would certainly follow. The prevailing German doctrine, however, is of a more positive character: the person who acts must have decided to act in any event whether the consequences ensued or not. This

doctrine is based upon the so-called *Willens-theorie*, whose most determined champion has been Hippel and which asserts that the consequences are willed because the person who acted was in "accord" with the eventuality. Opposed to this theory is the *Vorstellungstheorie*, numbering a strong minority of adherents, who assert that it is sufficient for the person who acts to consider the consequences as probable. But certainly not all consequences are willed which are considered probable. The will theory is also not free from difficulties but it probably has the merit of being closer to popular conceptions. It must be recognized, however, that the theorists who have distinguished between *Wille* and *Vorstellung* have perhaps advanced matters less than might be supposed, for the reason that the problem of proof makes it difficult to apply the distinctions.

Any consideration of the responsibility for intent apart from the responsibility for negligence would be misleading. In no legal system has responsibility been confined to intentional conduct alone. The tendency in earlier centuries was to consider some forms of gross negligence as at least presumptively intentional. Upon the basis of the somewhat obscure Roman *culpa lata* the Italian law constructed the doctrine of *culpa dolo proxima* to serve as a form of presumptive *dolus*. In the first period of the German common law absolute distinctions were made between *culpa lata*, *levis* and *levissima*. To escape the implications of his theory of guilt Feuerbach was eventually driven to invent a *culpa dolo determinata*, which served as a substitute for *dolus indirectus*. He also spoke of "conscious" negligence—an idea that has descended to modern German criminal law, where it now serves, however, solely as the boundary of *dolus eventualis*, having in itself no consequences for measuring punishment. Moreover it is only in modern law that the decision that an act was merely negligent does not as a rule entail at least milder punishment. Both the mediaeval Italian law and the German common law seem to have punished as a matter of general principle all crimes committed through negligence, unless indeed *dolus* was of the very substance of the crime. The practise under the German and French codes is to set the accused free when there is a failure to establish *dolus* unless the codes expressly or by necessary implication provide also a punishment for negligence in the particular case. Such express provisions are rare with respect to major but common with respect

to minor crimes. The contraventions of European codes are usually construed to require only negligence; while this result has been achieved by construction under the German and French codes it is provided expressly under the new Italian code of 1931. Again it is axiomatic that where *dolus indirectus* is recognized the field of criminal negligence will be small, as it is especially in Anglo-American law. Finally, it should be recognized that probably all countries can show some examples of responsibility not only for intentional or negligent crimes but for consequences alone; such provisions are usually found with reference to crimes of great public danger.

To realize the full reach of the doctrines of criminal responsibility it is also necessary to consider the effects of the doctrines of mistake or ignorance of fact or law. Their net result is often to make a violation of the criminal law intentional in only an artificial sense. The general tendency in all mature legal systems has been to excuse mistakes of fact. Of course the mistake must relate to the constitutive elements of the crime. If Jones intending to murder Smith mistakes Robinson for Smith and murders him, he is guilty of murder because the law forbids the killing of any human being. On the other hand, errors of law have been very rarely excused. However, for both the Roman law and the Italian law of the Middle Ages it has been disputed whether a consciousness of criminality was necessary. The Roman law seems to have allowed the plea of *ignorantia juris* to be made by rustics or women, an idea that was later recognized in various places. One of the causes for the controversy with respect to past systems is the difficulty of determining whether the excuse of ignorance or mistake of law represented a rule of responsibility or a presumption of proof. As has been seen, *mens rea* in English law was never held to mean that ignorance of the criminal law was an excuse. In the German common law down to the end of the eighteenth century the rule was *error juris non excusat*. Under the influence of Feuerbach the excuse was later actually admitted for several decades with the result that there set in a sharp reaction, which has restored the old rule in modern German law. In France exceptions are made in very unusual circumstances. The Norwegian code, however, provides that where there is a mistake of law the punishment may be decreased or even abrogated altogether. In fact many of the continental theorists are in favor of abrogating

or at least modifying the generally prevailing old rule, and some of the recent drafts of penal codes provide for milder punishment. But the problem is a difficult one. It is true that modern criminal norms are so complex that the average citizen cannot be expected to know them all. On the other hand, a relaxation of the old rule may very well endanger the legal order.

It is obvious that the part played by intent as an element in crime has depended largely upon the penal theory which has been current at any given time. Where the underlying principle has been retaliation, as in early societies, intent will play only a very slight part, since the purpose of retaliation on its rational side is to equalize the loss of the injured. Under the theory of deterrence—still the accepted theory of modern communities—punishment is directed against the will of the prospective offender, and hence it is conceived that it can be effective only if the offense is a matter which the will can control. When reformation is considered the object of punishment, intent must still be considered the essential element of a crime, because it is only the wicked will that can be the subject of correction and reformation. But even where contrition has made punishment unnecessary as a corrective, it may still be required from a religious point of view in order to purge away the pollution of the crime. A version of this doctrine appears curiously enough in such statements as that of Fichte that the criminal has a right to be punished and that he is therefore unjustly treated when this right is denied him.

The writers of the Enlightenment emphasized classification of punishments according to the grievousness of the wrong. They directed their efforts chiefly against the penal system which had grown up in continental Europe—an amalgam of the primitive desire of retaliation, of the newer concept of the duty of the state to protect itself against destructive forces and of the canonical theory of crime as a sin to be discharged by purgation. In theory the last element demanded a very delicate gradation of evil intent and a much more precise adjustment of punishment to individual deserts than did the system of the reformers. In practise, however, the continental penal system had degenerated into the arbitrary and often brutal determination of punishment by "reasons of state." Only too often not *dolus* but the *praesumptio doli* sufficed. The reformers demanded the fitting of the punishment to the crime and insisted upon

the attribute of personal guilt, which meant necessarily the presence of intent.

The modern positivist school of criminology has compelled a reconsideration of most questions of penology from a scientific point of view. Since this school refuses to admit the freedom of the will and considers the right to punish to be justified simply as a measure of social protection, it might be expected that the adherents of these schools would insist upon concern only with the happening of injurious consequences. The initial tendency, from which there has been a reaction, was to accept over-hastily theories of scientific determinism. The concept of intention may be retained by the most uncompromisingly scientific theory in order to express the fact that an individual has the power to select social rather than antisocial ends, although how and why he will use this power is not certainly predictable. This leaves the question exactly where it was in the most definitely "subjective" schools. The problem becomes one of inducing individuals to select social ends and of how they are to be treated when they refuse or neglect to do so. It follows that as long as in popular belief intention and the freedom of the will are taken as axiomatic, no penal system that negates the mental element can find general acceptance. It is vital to retain public support of methods of dealing with crime.

The positivists delight in pointing out the inconsistency of punishing a negligent act as a crime. Indeed it is difficult to see how such punishment can be reconciled with the postulate of guilt. Either the latter must be abandoned or a theory created which will fit the punishment of both intentional and negligent acts. A unified theory has usually been sought. Attempts have been made to see in the act of negligence a defect or a failure of the will. The application of the penal law to negligent as well as to intentional acts has been seen to be justified by its schooling of the will. The place of negligence in the theory of guilt seems to have attracted a particularly great amount of attention among Italian theorists. Two types of Italian theories may be distinguished: the theory of *prevedibilita*, which regards negligence as punishable because the offender has not foreseen a consequence that he might have foreseen—a view that is taken essentially by the positivists; and the theory of *causalità efficiente*, which insists upon guilt and finds it in the willing of the bodily action which may be

illegal. The latter theory really shifts the ground upon which the ordinary concept of intent rests; moreover the initial action may be involuntary or negligence may involve a total omission to act.

The question of criminal intent will probably always have something of an academic taint. Nevertheless, the fact remains that the determination of the boundary between intent and negligence spells freedom or condemnation for thousands of individuals. The watchfulness of the jurist justifies itself at present in its insistence upon the examination of the mind of each individual offender. Courts will doubtless long be compelled to separate from the mass of the community certain definitely recognizable irresponsible classes, such as infants and idiots, and to hold the rest of the community responsible for the direct consequences arising from their acts.

INTERALLIED DEBTS. *See* LOANS, INTER-GOVERNMENTAL; REPARATIONS.

INTEREST. *History of Doctrine.* Interest in its primary meaning is the payment for the use of money; more broadly, it may mean the return on investment in any form. In theoretical analysis it is generally taken to mean a "pure" remuneration for the use of money, or yield on money capital; pure interest is deduced from nominal interest by elimination of all elements imputable to cost or effort of administration, to insecurity of payment of interest or principal, to prospective changes in the purchasing power of money and to amortization necessary to maintain the principal intact. The word interest came into use in the late Middle Ages, replacing the term usury. The Greeks called the interest payment *tokos*, meaning offspring, whence Aristotle's statement that "money does not breed." The modern term comes from the Roman law expression for an indemnification for damage due to the delay in the interval (*interesse*) before repayment, one of the chief forms under which payment for loans came to be tolerated by canonical and civil courts. Interest in the modern sense was in the Middle Ages merely an important type of usury; since then the term usury has become specialized to mean interest at exorbitant or illegal rates.

In tribal and economically undeveloped societies there is a strong sentiment against lending

money at interest, which is usually prohibited as between members of the social group. The repugnance to interest has been ascribed to the danger of weakening the group in a military sense, since citizens capable of equipping themselves for war might be reduced to penury or slavery through debt. In Greece and Rome, where the ownership of landed estates was the gentlemanly source of income, the opposition to money lending was ostensibly grounded in ideas of social respectability; the opposition tended to disappear when money lending was regularly conducted on a scale which permitted the capitalist to live according to the genteel standards of the old aristocracy, and in the period of high civilization the law permitted interest at restricted rates. In the Middle Ages the prohibition was premised on religious and ethical principles. A loan was usually made under stress of special need for consumption purposes, and it was considered that to exact interest under such circumstances was to take advantage of a brother's need. Indeed it was admittedly a compromise with strict Christian tenets to require repayment of the principal. The doctrinal basis of the opposition to interest was found in the concept of objective value, any departure from which was looked upon as unjust. It was argued that no value could attach to the use of a consumptible good separate from the good itself, and money was regarded as consumptible because it could be used only by parting with it. Another argument was directed against the payment for time, over which no man could claim ownership. Church apologists therefore contend that mediaeval practise never seriously interfered with loans made in the course of business, where the use of funds had a money value to borrower and lender, provided only that the charge was "just." Moreover the payment of rent for the use of land or durable goods was never condemned by the churchmen or the canon law.

As trade and industry developed and a general loan market came into being, lending ceased to be treated as different from other market transactions. The role played by the Reformation in this connection has been disputed. Some attribute to Protestantism an important part in the disintegration of the mediaeval effort to apply ethical ideals to business relations, while others contend that it was rather a reaction, centering in relatively backward Germany, against the advanced humanistic tendencies of the Renaissance. In any case the prohibition of usury became increasingly difficult to enforce.

Legal devices and forms which to the modern student seem merely disguises for loans at interest came into general use; these forms were troublesome and their interpretation by the courts was uncertain. During the sixteenth century there developed a movement to abolish the prohibition; its literary champions were the Protestant leader Calvin and the French jurist Dumoulin. The first legal action was in England, where at the close of the reign of Henry VIII the prohibition of usury was replaced by a legal maximum [37 Henry VIII, c. 9 (1545)]; after a reaction this legislation was restored under Elizabeth [13 Eliz., c. 8 (1571)]. Other countries soon followed.

In the two following centuries the justice of charging interest was still the subject of controversy in voluminous theological and political writings but no attempt was made to discuss interest as an economic problem. The attack ran in the old moral and religious terms; and the defense was based on the supposedly evident fact that the use of money is a source of gain, is therefore of value to both the debtor and the creditor and hence should be treated by law like other articles of commerce. In the latter half of this period the demand for regulation was based more on mercantilist grounds: English writers, for example, argued that low interest cost was necessary to help English business to compete with foreigners in the export trade.

The next stage in the historical development of interest theory, comprising the work of the classical school of economists, extends for more than a century after 1776, the date of publication of Adam Smith's *Wealth of Nations*. Writers of this school contributed little toward the formulation of an integrated distribution theory, in which interest theory falls. They regarded the problem of distribution not as one of pricing services furnished to production but as one of dividing the total income of society into the shares of the three economic classes which they recognized. The landlord's share, rent, was explained as a "surplus," on the ground that it did not enter into the price of the final product stated in terms of pain cost. Wages were explained by the simple observation that the laborer must live. Thus the way was opened for treating the share of the capitalist, which was called profit, as a residue after the other shares were paid. J. S. Mill, for instance, regarded it as a settled doctrine that profit arises because labor produces more than is required to sustain the laborer; in other words, because

industry produces more than the laborers get. Yet the explanations of wages given when the topic of wages and not that of profit is explicitly under discussion run in very different terms; the most famous of these explanations, the wages fund theory, even assumes profit as previously determined (or negligible) and makes the wage share either the total capital or the portion actually used to employ labor. The classical school never faced the problem of the nature of capital as a quantity and hence could not have said anything very illuminating about the rate of interest. Their general conception of capital was that, like products generally, it is produced by labor and hence is really the embodiment either of a certain quantity of labor or of the subsistence goods on which the laborer lives while performing that labor.

In contrast to their vagueness regarding fundamentals, classical writers showed profound insight in many partial analyses and especially in practical conclusions. N. W. Senior in particular, following up hints in Ricardo, developed brilliant ideas in connection with capital and its return; and his lesser known contemporaries, Rae and Longfield, came near to explaining interest on the ground of capital productivity. Senior made the general character of capital and its function in production one of the four fundamental propositions from which he wished to develop the whole science of political economy. In his effort to bolster up the pain cost theory of price at one of the weak points recognized by Ricardo, Senior argued that the essence of capital as an element in cost is the pain of abstinence. Yet it is indefensible to attribute to him, as Böhm-Bawerk does, an abstinence theory of interest. Besides his clear and repeated explanations of the productivity of capital Senior stated expressly that abstinence has nothing to do with the return after capital has changed hands through gift or inheritance. In his discussion of profit he assumes that the sacrifice of abstinence would prevent the return from ever falling to zero but explains the actual level first as a residual and finally, after a very tortuous argument, by the proportion between capital and labor in existence; this is true but incomplete.

Economists of the classical school achieved progress also in their discussion of the various elements into which the gross return on capital must theoretically be analyzed. Adam Smith himself made it clear that in typical cases

part of the return must be treated as essentially a wage—later called wage of management—and another part as compensation for risk, true interest being different from both. J. S. Mill even had fairly clear notions of a further differentiation between payment for risk in the sense of an insurance premium against a recognized hazard and mere accidental deviations from a normal return because of miscalculation or unforeseen changes. These beginnings developed into the tendency to treat profit not as the gross income including interest, which was the usage of the classical writers, but as the final residual income of the entrepreneur after a deduction of both interest and wages of management.

The confusion in the classical reasoning between the causality problem of the market value of services of various kinds and the ethical question of remuneration for sacrifice explains in part the contemporaneous development of another system of economic thought which treated all property income as exploitation of labor. The socialistic and anarchistic schools, from Godwin and Thompson to Louis Blanc, Rodbertus and Karl Marx, have held that the modern economic order based on "economic freedom" has merely substituted the economic power of property ownership for the physical and military power of slave owner and feudal lord as a means of enabling the upper class to live by the sweat of the masses. Practically every detail of socialistic theory can be taken almost verbally out of the classical treatises, which habitually referred to labor as the producer of all wealth. Abstinence as a justification for interest was particularly vulnerable to ethical attack, since most of the abstaining seems to be done by persons who have first consumed all they can or at least more than they need. This point was used with telling effect by Lassalle in Germany. Whether they do or do not explain how property income is possible exploitation theories do not offer a cause and effect analysis of the proportions obtaining between property and labor incomes. As to the ethical challenge which they present, it goes without saying that in competitive society every income is based on economic power. Whether or when or how far property income is defensible on grounds of abstract right or of social expediency is a question to be answered by the ethical or political philosopher rather than by the economist. Interest is merely a form of payment for the use of real wealth transferred from one person to another. Hence no special objection can be

directed against it; its merits and demerits are those of private property and of a social order based on ownership. Moreover it is questionable, at least in theory, whether a clear cut distinction can be drawn between property and labor incomes. As was emphasized by Smith and Senior among the classical economists, a large part of the earning power of individuals paid for as labor is really the fruit of an investment no different in principle from any other; and another large part is the result of inheritance or chance.

Discussion of interest theory during the generation preceding the World War centered around the work of Böhm-Bawerk. Before him the English economist Jevons had given a mathematical version of a type of productivity theory along with a very penetrating discussion of the relative valuation of present and future goods. But Jevons' work received only limited recognition until similar views were presented in more popular non-mathematical form by the Austrian school, which for interest theory practically means Böhm-Bawerk, although Wieser's variant of the productivity theory is more in harmony with accepted doctrine of today. While it appears to rest on the preference for present as against future goods Böhm-Bawerk's view of interest is really a productivity theory, since the possibility of productive investment is the most important, at least from a short time point of view, of the three "reasons" advanced by him for such a preference. Jevons, Böhm-Bawerk and the writers who have followed their line of approach interpret capital as meaning essentially the substitution of more indirect or "roundabout" for more direct methods in production, as an increase in the time length of the production process with a resulting increase in efficiency of the use of primary factors. This is similar to the classical conception of capital, except that the earlier writers lacked the notion of correlated variation in elements of complex situations; they tended to think of capital as conditioning production in an absolute sense rather than of the amount of product as subject to increase by increasing proportions of capital. Böhm-Bawerk also labored to establish a distinction between the psychological preference of present to future and the notion of abstinence. He had great influence, especially in the United States, where particularly Fetter and Fisher took his work as a point of departure in constructing time preference or eclectic theories.

In recent years attention has been centered on Schumpeter's theoretical construction which regards interest as belonging essentially to a dynamic economy. The innovators among the entrepreneurs who bring forward new and more efficient methods of production and business management obtain a surplus over cost, a part of which is returned in the form of interest to banks and other suppliers of capital funds without which the new projects could not be executed. In the absence of new inventions and other advances there is according to Schumpeter no room for interest. In application to statics Schumpeter's theory is similar to Marshall's in that it deals with the long run equilibrium rate; while for Marshall this rate is determined by the interrelation of "waiting" and productivity, Schumpeter assumes that the rate is zero. It is difficult to see the reasons for this assumption: there is no limit to the use of capital even in the absence of new inventions, although the rate of return would of course fall indefinitely low as investment proceeded. Intellectually Schumpeter's dynamic interest is related to subsequent attempts to explain interest on loan funds in terms of banking cost.

General Theory. The theory of interest begins properly with two facts. The first is the existence of various kinds of goods, the use of which has economic value as distinct from the objects themselves; it is actually bought and sold, and the payment, based on the length of use, is called a rent. The value derived from possession of an item of wealth for an interval of time may be of three main kinds: immediate satisfaction, as in the case of durable consumption goods; assistance in producing other goods, as in the case of producers' goods; increase in sale value of the item itself through time, whether through natural increase in its quantity, improvement in its quality or change in the conditions of supply and demand. An effective increase in value must of course exceed any direct cost incurred in connection with it. The second fact is that many kinds of rentable goods can be produced under conditions and at a cost more or less accurately known. Both of these facts are of a technical sort; that is, they are data for the interest theorist, although they may be problems for the business manager.

The peculiar feature of interest which makes it a special problem for economics is that it is not a rent paid directly for the use of property in the concrete sense but is a payment for

the use of money (and as such takes the form of an abstract number, a ratio or percentage). Yet while the borrower obtains and repays a money loan, it is the use of goods which the borrower wants and gets by means of the loan. If loans for consumption are left out of account, as they may well be since under modern conditions their terms depend upon those of loans for productive purposes, the rental or yield of goods the use of which is obtained by means of the loan provides under normal conditions the income paid out in the form of interest. Competition tends to bring about equality of return from equal investments; the ratio of this equalized return to investment is the rate of interest. Since the income from property is a given fact, the problem of the rate of interest is that of explaining how the amount of the investment, the capital, is determined in monetary terms; in other words, it is the problem of the evaluation of productive property.

The psychological or time preference or *agio* theorists solve the problem of capital according to the immediate facts of demand and supply, buyers' and sellers' offers, viewed psychologically. There is in the market, they argue, a certain aggregate of such goods, on which the owners set a certain estimate and which prospective purchasers likewise value according to individual tastes and means. The value set on an item of wealth is of course the value of the stream of income which it is expected to yield in the future in comparison with similar units of service or satisfaction at the moment. The competition of buyers and sellers will set on income yielding wealth a price which makes the amount demanded equal to the amount offered at that price. This price involves a uniform market rate of discounting future values. Thus if at the equilibrium point it takes \$1 in hand to buy \$1.05 payable one year from date, it will also take \$20 to buy a piece of property yielding a perpetual income of \$1 per year; all other income bearers will be valued on the basis of the same arithmetic proportion and the rate of interest will be 5 percent. Taking into consideration the ordinary form of loan, involving repayment of principal, and ordinary investment and accounting policy, which reckons return only after full provision for maintaining the investment in perpetuity, the correct standard for comparison is that of a perpetual income of given size with the value of the wealth yielding such an income. As regards any particular item of wealth the process of evaluation takes the

form of capitalizing its income, with allowance for its expected duration, at the general market rate.

The productivity theorists approach the problem of capital valuation from a different angle. They do not question the validity of the time preference reasoning but find that it lacks finality as an explanation under actual conditions. They observe that as regards unique and non-reproducible durable goods there is no objection to the capitalization theory of evaluation, as a first approach at least; and if all durable wealth were of this character, in other words, if there were no possibility of producing it, there would be no objection to the theory as a final explanation. But the possibility of more or less closely reduplicating existing types of wealth or of producing new types of wealth yielding future satisfactions places the matter in an entirely different light. If the capitalized value of any income bearer is more than the known cost of producing items yielding an equivalent income stream, people will instead of purchasing the existing items set about producing new income yielding goods and these will sell not at their capitalized value but at the lower level set by cost of production. Conversely, no new wealth will be produced for the future unless the capitalized value of the expected income is greater than the cost of production. Hence if new wealth of more or less durable form is actually being produced, all such wealth must sell under competitive conditions for precisely the cost of producing items of any physical type yielding the same income (after all deductions necessary for perpetual maintenance).

If goods are valued for the sake of their future yield, then their physical character is a matter of indifference; all such goods viewed economically form a perfectly homogeneous class, and the value of any item depends only on the amount of the future income maintained in perpetuity. It is characteristic of the psychological theory itself that only the future income as such is valued. Hence if it is possible to produce any goods yielding future income, the cost of production of these must determine the value of all goods of the class. Under equilibrium this value will be equal to the value as determined by capitalization, but that is because the supply of any good yielding more than interest on its cost will be increased as long as this relation holds. For non-reproducible goods or goods yielding less than interest on reproduction cost capitalized value with rate

determined at the investment margin and cost of production of equivalent goods are in fact different ways of saying the same thing—as long as any kind of durable wealth is actually being produced. In a society or a world in which there is actual growth the rate of interest is determined by or simply is the ratio between perpetual annual income and the cost of income yielding goods at the margin of growth. New investments will not be made unless they offer more than the purchase of old ones, which forces the writing down of the old ones to the level of the new.

That interest is the ratio between perpetual income and cost at margin is true only under "perfect competition." In actual markets economic adjustments work themselves out more or less slowly and imperfectly. Perhaps the most typical result in real life is to "overdo the thing" in expanding or contracting investment and thus to set up oscillations in the rate of return. Since neither the yield nor the cost of new wealth items can be exactly foreknown at the time when productive commitments are made, any piece of new property may from the start yield more or less than the interest on its cost and the longer the item lasts the more uncertain becomes the relation between return and cost. When an unforeseen change in conditions occurs, the owner of wealth affected by it receives a speculative profit or suffers a speculative loss through appreciation or depreciation of his investment. The capital value of an investment is measured directly in the case of new, free capital just flowing into concrete forms of wealth and is arrived at by the capitalization process in case of all concrete items of wealth in existence.

Another variant of the productivity theory is that advanced by Jevons and Böhm-Bawerk, which states the basic facts in terms of the length of time elapsing between the application of labor (and any other primary factors) and the enjoyment of the fruits and in terms of the efficiency in the use of these factors as a function of the time length of the production process. There is obviously a rough correspondence between this notion and the one expounded above which relates the cost of income yielding goods to the net return obtained from their utilization. While Böhm-Bawerk's view may be more appropriate for some theoretical analyses, it is fatally handicapped by the lack of a general and accurate conception of the length of the production process. In a certain loose historical sense capital goods may be resolvable into labor and

time or into labor, "nature" and time; but no particular item can be so treated for the simple reason that in the production of any capital good the use of preexisting capital goods is always involved. There is no working distinction between capital and other factors. Without the presence of the element of uncertainty all natural resource values at once become capital; from the standpoint of the market itself they are capital in any case. Much the same must be said of a large element in labor power, which is a produced good; it is social institutions which justify any separation of labor from capital, as the case of the slave suffices to prove. Nor is there a computable time length of the production process in any particular case; still less is there an average length in a literal sense. Much capital is completely permanent unless made obsolete by unpredicted changes, and a series containing infinite items cannot be averaged. An average can be found only theoretically by dividing the annual maintenance and replacement into total capital value, a calculation which presupposes that all the data of the capital and interest relation are previously known. In fact it is always intermediate products, not the application of labor over more time in a literal sense, which produce the increase in output. Interest must be treated as the productive yield of capital, defined and measured by its cost or the cost of equally productive items, in terms of sacrificed immediate goods.

Eclectic theories generally make use of the demand and supply scheme of analysis to combine the psychological and the productivity explanations of interest. To complete the exposition it is necessary therefore to consider the problem in terms of demand and supply. In this connection it is not clear what is supply and what is demand, what is being priced and what is the price, since both the commodity and its price are stated in money terms. One may regard interest as the price of the commodity, use-of-capital, or savings as the price of future income. The former is the more familiar view: the supply of the commodity, use-of-capital, comes from saving, while the demand for it comes from the people controlling opportunities for investment.

In this view the supply is the total amount of productive wealth in society, and the savings made in any short interval constitute merely a small addition to it. The rate of saving, which is only the rate of increase in the supply of capital, may or may not depend on the interest

rate; but in any case the supply as such keeps on increasing always, at all rates. The supply is thus highly inelastic: strictly speaking, it is absolutely inelastic at any instant of time. Demand, on the other hand, is highly elastic, since it is indisputable that the opportunities for investment would absorb large amounts of capital with only a gradual lowering of the rate of return. Hence demand determines the price, supply being a "datum," a given condition but not a cause.

The other view of the interest transaction as a purchase of future income for present wealth in hand corresponds to the statement of the problem as essentially that of the valuation of productive wealth. Now, if the commodity is future income, supplied through the production of income yielding goods, and the demand comes from savings, then the supply is indefinitely elastic and the demand inelastic. The virtually unlimited possibility of using more capital in production means that future incomes can be provided in correspondingly large volume at a slowly increasing cost. Other things being equal, it is true that a given investment—that is, cost incurred—does tend to yield income at a decreasing rate as the amount of investment increases, since capital as a factor in production is subject to diminishing returns; but this decrease is very slow in comparison with the total magnitudes involved. It appears, for example, that in the United States the elasticity of demand for capital is around unity; that is, the total supply of capital, which includes the entire national wealth, would have to be doubled before the interest rate would be reduced to half its value at the beginning of the test. This would call for saving for a full generation at a high rate, so that it is correct to consider the supply of future income at a given time as practically unlimited, indefinitely elastic. The demand for future income, represented by the amount of savings available for investment, is at a given moment narrowly and almost absolutely limited. In the theoretically perfect adjustment it would at any instant be zero in absolute amount, a mere rate of flow, disappearing in investment as it appeared in saving. In this situation, as in the case of any commodity produced under nearly constant cost, demand conditions—the psychological comparison between present and future—can operate only to affect the volume of savings without an appreciable influence on the price at which they are invested. Men with different estimates of future in terms

of present satisfactions will save different amounts (or conceivably consume varying amounts of capital already in hand); but the effect on the interest rate of the resulting changes in total supply of capital will in any short interval, even a year, remain negligible.

In the long run the yield on new investment depends in part on the amount of capital previously invested (in all past time) and thus reflects variations in the amount of savings in the past, which may be said to depend on comparisons made in the past between present and future. This does not affect the conclusion that at any given time the supply of capital is a datum and that the current psychological estimates have no effect on the rate. Moreover serious objections arise with regard to the historical view itself. At the rates of pure interest which have obtained in modern times it would require a generation for a saver to get in income a total sum equal to that given up in making his investment. In reality the net accumulation of capital depends on the fact that savers maintain their capital and leave it behind when they die. At most they consume the income; and the classes which make substantial savings even reinvest a part of income through life. It does not seem very realistic to call the decision to save and invest, looking beyond one's own life, a choice of future rather than present satisfaction. It may of course be put in that form in order to construct a rationale of economic choice. But there is no reason to believe in the reality of "impatience" or of preference of present to future as a general principle of conduct, if conditions are correctly stated to isolate this comparison from other factors, particularly if interest itself is eliminated as a factor. A realistic discussion of the motives involved in decisions as to saving would run rather in terms of interest in security and power, of living standards, of forms of social emulation and of similar facts of social psychology and culture history.

Nor is it legitimate from a long time point of view to assume that other things remain equal in connection with the law of diminishing returns on investment. As new investment tends to lower the point of equilibrium on a descending demand curve for capital, other social changes are always and inevitably acting to change the position of the curve itself. In fact these two sets of changes have roughly offset each other through history, so that there has been no clear trend of the interest rate upward or downward,

especially in the modern industrial era. The relative constancy of the interest rate has aroused the curiosity of many economists and provoked much speculation. An older view, held by Henry George and Alexander Del Mar, found a physical basis for interest in the average rate of growth of animals and plants, while Cassel has made the ingenious suggestion that it may be connected with the length of human life. A sufficient explanation is found in the tendency of practically every form of social progress both to make saving easier and to increase the demand for capital, raising the curve vertically if drawn with quantity on the base line. Even if invention and all forms of social progress ceased and saving went on at an indefinitely high rate, the interest rate would never fall to zero; for there is no limit to the possibility of using capital to increase the supply of innumerable commodities which could never become free goods. There is no empirical evidence or abstract reason even for the belief that under such conditions the point of long run equilibrium—a naturally stationary supply of capital—would be reached. It appears therefore that Marshall's long run equilibrium theory is just as untenable as the short or long run psychological theories.

The long run may be discussed only in the manner of the philosophy or theory of history. The interest rate tends to fall or rise as the effect of accumulation runs ahead of or behind the effects of other types of social change, notably increase of population, development of natural resources, invention of new technical processes and opening up of new fields of demand. Accumulation itself likewise depends on the general movement of taste and the people's outlook on life. Here analysis of the type of price theory in terms of tendency toward equilibrium under given conditions has no applicability whatever. The problems and theories are necessarily sociological or institutional, and comparatively little help may be expected from any sort of deductive theorizing yet devised.

From the standpoint of computation there are two ways of looking at the interest relation. One is the everyday view of the interest loan or other investment in which the investment itself is maintained permanently. From the gross yield of the property is deducted, first, all operating expense; second, direct upkeep cost; and, finally, a sum which accumulated to the point of retirement from service will replace the original investment. The remainder is a

perpetual net income; when divided by the cost of the property it shows the rate of interest. It is evident that both the cost of a capital good and the annual contribution to a sinking fund for replacing it involve the interest rate itself. Another method of formulation is more suited to the bond market and amortized loans. In a continuous market under stationary conditions any investment can theoretically be made, continued or realized at will; hence the accumulated cost (less return if any) up to any point in time must equal the discounted net return looking forward from the same point. Both of these facts may be stated as equations with the interest rate as the unknown; a few algebraic operations would simplify the two equations into the same form. It is most realistic to take as the equating point the moment when construction is complete, equating past cost with future return. If S dollars per year are saved and invested for C years and the resulting property yields a net rental of R dollars per year for a service life of L years (with no scrap value), then $SA^C(A^C - 1) = R(A^L - 1)$, where interest is compounded annually and for simplicity A is written for $(1 + i)$, unity plus the interest rate. The first view more nearly corresponds to the realities of the situation than does the view of discounting. The essence of the matter is that artificial capital goods yield during life a total net rental greater than their cost; the difference is, roughly speaking, interest on the cost for the period, which must be distributed equally through time. To do this exactly calls for compounding continuously instead of annually by the use of the same type of formula as that given above.

Historical, Dynamic and Sociological Aspects. A survey of the general theory of interest serves to emphasize the vast territory which would still have to be covered in order to give much concrete information about the factors determining the rate on a loan under varying historical and social conditions or even on loans of a different character in the same country and year. In the first place, the general theory itself is abstract in a sense beyond that implied in generality: it explains in terms of given conditions which are taken for granted in every aspect except the quantitative. Back of the motives affecting choice immediately, at the time and place in which the decision is made, is an infinite complex of why's and how's, ultimately including most of human history. A final explanation of any economic choice would have to

include these factors in their concrete character, giving a sociological or institutional treatment instead of one based on the analogy of mechanical forces. In the second place, there are considerations which affect the terms of loans and investments in greater or less degree in different classes of cases, large or small, running into unique circumstances of the individual case. Some of these considerations are of such a character as to supplement the general theory, some rather of the nature of interfering forces which prevent competitive tendencies from finding effective expression.

Even in the most highly developed loan market hardly two loans are alike within significant limits, and many divergent types must be recognized. Superficially viewed, this is something of a paradox, since the commodity dealt in is the use of wealth in its most abstract form; yet loans are in fact much less amenable to standardization than many concrete commodities, such as wheat. But in addition to the unlimited diversity of circumstances among different loans and capital commitments at any given moment there is the supreme fact that they all look to the future for their value. And with reference to the future both an intrinsic uncertainty as to facts and an even wider divergence of human opinions and attitudes defy specification.

Even in the most advanced countries there is no one general interest rate and no one general money market, although there is a perfect market for certain securities dealt in by name and an approximation to a general market for loans of very short duration and unquestionable security. In practise in virtually every case the making of a loan is a matter of negotiation, and negotiation is the antithesis of what happens in the perfect market of economic theory. A few governments and large corporations are in a position to issue securities within limits and to offer them to the public through an impersonal marketing organization, but even with them a new loan of considerable size will be floated by negotiation. Even within the field where standardization of loans is carried farthest, it is normal for the bank rate to be about double the rate on the best bonds, while call money may go at a fraction or at a multiple of the latter. Farm mortgages plod along very steadily at an intermediate level, while the others fluctuate in their respective ranges, largely independent of one another. Outside the field covered by organized markets the loan rate may be almost rigidly uniform through widely varying conditions—an

instance of the "customary price" in connection with loans—or may fluctuate within the widest limits from case to case; the latter is of course the more usual situation. Generally the rate is much higher than in organized markets. Thus in the south in the United States Negroes are said to borrow \$5 at the beginning of the week and repay \$7 at the end of it, an interest rate of 40 percent per week. Loans made to the very poor on furniture and similar articles are said to range from 100 percent up. In instalment selling, a method by which a large fraction of the automobiles and a smaller fraction of many other goods are regularly marketed in the United States, the terms involve a rate of interest from 11 to 40 percent; it is to be noted that these rates are charged to persons of good credit standing and on quite sizeable sums. The Uniform Small Loans Act, designed to curb the exactions of loan sharks and adopted by over twenty states, prohibits interest above the monthly rate of $3\frac{1}{2}$ percent.

Because of the overwhelming difficulty of the task no study of the general interest rate through history has as yet been undertaken; even the investigations of limited periods in the history of single countries are not detailed enough to permit confident generalization. Until the nineteenth century the available information relates to specific cases which may or may not be typical; yet even when allowance is made for their uncertain representative value, the data are sufficient to illustrate the extreme divergence of nominal interest rates in different epochs. This, however, should not be taken to imply qualification of the statement that the rate of pure interest has been surprisingly constant through history.

Thus W. H. Dubberstein's study of numerous clay tablet records extending over many centuries found that in later Babylonia the rate of 20 percent recurred with monotonous regularity; the rate was twice as high in the neo-Babylonian and Persian periods (650-325 B.C.). In Ptolemaic Egypt the regular rate was 2 percent per month (Westermann, W. L., *Upon Slavery in Ptolemaic Egypt*, New York 1929, p. 32). In Greece the rate at the time of Solon was about 16 percent; at Corcyra in the second and third centuries B.C. loans on good security commanded 24 percent while the common rate at Athens in the time of the orators was from 12 to 18 percent (*Palgrave's Dictionary of Political Economy*, vol. ii, new ed. London 1923, p. 429). Mommsen states that in Rome the rate in the time of

the monarchy was probably about 10 percent per annum (*The History of Rome*, tr. by W. P. Dickson, vol. i, new rev. ed. New York 1905, p. 195). Under the later republic interest was usually stable and low, normally ranging from 4 to 6 percent. In Asia, where invasions, inefficient government and indirect business methods made for insecure possessions, 12 percent was a low rate even in times of peace (Frank, T., *An Economic History of Rome*, 2nd ed. Baltimore 1927, p. 294). The Byzantine law of Justinian limited the rate of interest to 12 percent for loans on cargoes, 8 percent on loans for business purposes and 6 and 4 percent in other cases (Ashley, W. J., *An Introduction to English Economic History and Theory*, vol. i, 4th ed. London 1909, p. 210). In the early Middle Ages Byzantine commerce could raise money at the moderate rate of 8 to 12 percent; the rate was lower still in the tenth century, which was quite unusual for the rest of Europe (Boissonade, P., *Life and Work in Medieval Europe*, tr. by E. Power, New York 1927, p. 51).

For western Europe in the Middle Ages it is difficult to make definite assertions regarding the interest rate, because the fact of interest was concealed or disguised in consequence of the usury laws. Interest was certainly high for most loans. Ashley states that the rate which the Jews were permitted to charge in England in the thirteenth century was two pence per week on the pound, or approximately 43 percent per annum (p. 203). According to Sombart the rate permitted to the Jews by a regulation of 1243 in Provence was 300 percent, while that specified by the emperor Frederick II the next year was 173 percent (*Der moderne Kapitalismus*, 2nd ed., Munich 1916, vol. i, p. 626). In contrast Boissonade states that during the Hundred Years' War commerce in Italy and Germany obtained credit at the rate of 4 to 10 percent (p. 288), and M. M. Knight asserts that commercial interest rates in southern Europe became standardized from the thirteenth century at 10 to 17 percent (*Economic History of Europe to the End of the Middle Ages*, Boston 1926, p. 116).

For the Renaissance and the following period data have been made available by Ehrenberg (*Capital and Finance in the Age of the Renaissance*, abr. and tr. by H. M. Lucas, London 1928) from the Fugger records and other sources. Ferdinand and Isabella sold annuities bearing 10 percent (p. 24). In the sixteenth century the rate on commercial loans on the Antwerp bourse, an effectively organized market, was from 2 to 3 per-

cent per fair, i.e., 8 to 12 percent per annum (p. 247). In a list of thirteen short period loans made to various governments between 1519 and 1521 the rate varies from 7 to 27½ percent besides "considerable" brokerage charges (p. 259-60). In the decade 1532-41, it is asserted, there was a slow reduction in the rate of interest, which varied from 13 to 20 percent in 1535-36 (p. 265). For the years 1546-47 there is available a list of loans in which the Fuggers were borrowers, chiefly from other south German banking families, and another list of loans by the Fuggers to various courts and governments; in the former the rate varies from 8 to 10 percent, in the latter from 11 to 13½ percent (p. 269).

The first modern bank, the Bank of England, was founded at the end of the seventeenth century in connection with the first funded state debt. From that date one may speak of a general rate of interest in a sense not previously possible, especially as London has since been the central capital market of the world. The transactions of such a bank and dealings in such funds involve a publicly known rate, and publication is the main consideration in standardization. The initial loan to the state, which was a new dynasty of questioned status engaged in a major war, was at 8 percent; but the rate fell rapidly and after the conversion of 1750 the English government was borrowing from the bank at 3 percent. In 1751 the government issued 3 percent consolidated annuities; but later the consols fell far below par, fluctuating with the wars and the progress of the industrial revolution. In Holland in the second half of the eighteenth century, as Adam Smith observes, the government was borrowing at 2 percent and private persons at 3 percent (*Wealth of Nations*, bk. i, ch. ix).

Modern conditions may be said to begin after the post-Napoleonic settlement and the final establishment of English coinage on a gold basis. Since the first quarter of the nineteenth century information on interest rates becomes increasingly abundant both for the London money market and for other markets. An analysis of such data reveals the existence of permanent differences between rates on the same type of loan in different markets as well as between rates on different types of loans in the same market. Only when allowance is made for the fact that each type of rate in each money market seems to have its own zone of variation do the fluctuations of the rates appear more or less cor-

related. If the level of the interest rate after 1825 is to be judged by the yield of British government consols, which by many authorities is taken as the nearest available approximation to pure interest, it will be found to have fluctuated between 3 and 3½ percent until the 1880's; the trend after that was downward until the turn of the century, when the rate began to rise, reaching its customary level by 1910. Similar data for the United States are available only from the last quarter of the nineteenth century. Thus F. R. Macaulay's index of bond yields, based on the quotation for the "best" railroad bond—that is, the one with the lowest interest rate—indicates that the interest rate was approximately 5½ percent in 1875; it fell fairly steadily to about 3½ percent in 1900, rose to about 4 percent by 1914, reached its post-war peak at 5 percent in 1921 and has fluctuated since in the neighborhood of 4½ percent.

There is no great difficulty in indicating the general lines along which changes in the general interest rate and divergences between various types of nominal interest rates are to be explained. The most important immediate causes producing changes in the interest rates in modern times (acting apart from or through the intermediary of real investment opportunity and real savings) have been the fluctuation of business conditions in the now unpleasantly familiar cycle, war and the opening up or saturation of new fields of investment, of which the railways are the stock example. The main causes of divergence in the rate from one type of loan to another at a given time are included in the categories recognized by Adam Smith and his followers; namely, trouble or expense in connection with the loan and uncertainty of payment of interest or principal. To these should be added the case of monopoly: special conditions may cut a borrower off from the general market and give a lender power approaching that of exclusive control over a necessity of life.

Administrative expense clearly accounts for the excess of the bank rate over that on good bonds. Indeed some economists have held that the interest rate under modern conditions is determined by the operating expenses of banks, a statement to be interpreted in connection with the entire theory of the relation between currency and interest. Again, a pawnbroker may lend at a rate per month equal to that yielded in a year by good securities and still make no more than the same net rate of interest, if account is taken of the expenses incident in the conduct of

a pawnshop and the competitive wages to which the pawnbroker may lay claim.

Uncertainty, which is a better general term than risk, affects more or less every loan or investment, depending especially upon how far into the future the commitment looks. The measurable element of uncertainty, risk in the proper sense, can be eliminated by applying the insurance principle in some form. But the subjective and individual element of uncertainty is not susceptible to standardization; it is a matter of how much confidence one feels in his opinions about the future course of events and of how much courage he has in acting upon his convictions. Uncertainty, more or less connected with expense, explains the major differentiations in interest rates between different sections of the money market. Rates are high in new countries and frontier areas, partly because experience offers no basis for accurate prediction of the future or objective estimation of risk and partly because the lenders typically live far away in the older centers and have to depend on sources of information in which they place limited confidence. There is also the cost of obtaining, transferring and validating such information as is available as well as special mechanical costs of administration at a distance. Such considerations also apply as between loans separated by other than geographical distinctions, particularly between older and newer types. In addition most capitalists are more informed or feel more confidence in their information about certain types of investment than about others. The fact probably does not produce important permanent differences, but it certainly retards the flow of capital from one field to another in response to rapid changes in real investment prospects.

One phase of the factor of uncertainty has to do with changes in the general price level, to which Irving Fisher has given special attention. Apart from any connection with general business conditions changes in prices should obviously affect the interest rate, if they are generally foreseen. If the value of money is expected to fall between the contraction and the maturity of a loan, the borrower should be correspondingly more disposed to borrow and the lender less disposed to lend until the rate goes high enough to compensate for the change. Perfect foresight would clearly mean foreknowledge of conditions during the period of the loan and not an adjustment of the rate on the assumption that the rate of change at the time the contract was made

would hold good forever, as Fisher assumes; but the latter interpretation of foresight may more nearly describe the way men think and act. People do not have the necessary foreknowledge, in the full sense of the term, and even in the face of actual changes they inveterately tend to consider the value of money as absolute unless it is visualized in some concrete speculative price, such as the quotation of one currency in terms of another. As a matter of fact, to the extent that the effects of anticipated changes in the value of money do appear in the history of interest rates and prices they are largely due to an indirect influence; namely, the relation between price changes and business conditions. Rising prices mean large profits, because wages and other basic costs tend to lag, and hence an increased demand for loans. Also capital owners may be more disposed to go into business for themselves rather than to lend their funds at a time when things are "booming," which would mean a reduction of apparent supply as well as increase in demand.

However the matter is viewed, the problems of interest, of the price level and of the business cycle overlap. Certain economists, notably Fisher, consider the business cycle essentially a phenomenon of price level changes, a "dance of the dollar"; while others would regard price changes as effect rather than cause, some of them suggesting even that the primary phenomenon is precisely the artificial stimulation of the creation of capital through credit expansion. The obvious relationship between the interest rate and cyclical price movements arises from the fact that in the modern business world the great bulk of the medium of exchange consists not of money in the primary sense of a money commodity, such as gold, but mainly of bank credit and to a lesser degree of government credit. Bank credit, whether in the form of deposits or of banknotes, represents a right to obtain gold on demand and under a gold standard depends for its validity on the power of the banking system to make this right good. But only a fraction of the normal total volume of bank deposit and note obligations is represented by gold stored up anywhere to meet the demand; the primary backing of such credit consists of the presumably liquid assets of borrowers from banks. Deposits and notes for the system as a whole are created through loans by banks to their customers. Since the banks lend money chiefly for productive purposes, taken in the broad sense to include merchandising, there exists a close

and inseparable connection between the phenomena of money and circulating credit on the one hand and those of capital and interest on the other; a new bank loan is an addition at once to the supply of effective currency and to that of effective capital, for the proceeds are used by the borrower in the same way as is a loan based on real saving.

If "other things remained equal" it would be fair to argue that the creation of capital by bank loans represented a tax on the owners of money through a reduction in the purchasing power of each unit. For the writing of slips of paper and the making of book entries by bank clerks do not directly create any more goods or productive capacity, and the new purchasing power placed in the hands of borrowers must be subtracted from that of the effective money previously in circulation; the dilution of the circulating medium must manifest itself in a rising price level. It is arguable, however, that new purchasing power may serve to bring into use existing wealth or productive power previously idle and so to increase the total output and circulation of goods instead of raising prices. Then in effect the new real capital created through the loan will represent no real cost to society as a whole other than what may be involved in putting idle capacity to work, and this may even be a gain.

Apparently both of these effects are represented in some degree in what actually happens. An expansion in the volume of bank loans is associated with both an increase in the total volume of production and a rise in the price level; the latter is higher than it would have been in the absence of credit creation, even though it may not rise absolutely. In the past business expansion financed by created media of exchange has turned out to be a process which ultimately reversed itself, giving rise to cycles. Precise proof of what is causal in the process depends on a very accurately measured statistical knowledge of the sequence and timing of changes or upon the successful control of the phenomena by actual manipulation of some element in the situation. Until such proof is available it is not possible to say positively even that the process is necessarily self-limiting and reversing or that this feature is necessarily connected with the use of credit currency and with expansion and contraction in its volume.

For the student of interest the important fact is that all these phenomena exert a large and at times overpowering influence on the loan

market, acting on both the supply and demand sides. One effect is a fairly sharp separation between short term and long term loans, the latter being relatively much less affected. In the market for short term loans the fundamental investment conditions, with which the general theory of interest is concerned, may be eclipsed at crucial points in the cycle by the special situation generated by the cyclical movement. The demand for loans may be dominated at the moment by the state and prospects of business from a cyclical standpoint and by the necessity for business men to meet outstanding obligations and keep solvent. The supply of loanable funds may be just as completely dominated by the state of bank reserves and the general banking position and by the vicissitudes to which money incomes in general are subject because of monetary changes.

The effects of the cycle exercised through phenomena associated with long term capital are more varied. The fluctuations of profit connected with cyclical movements of business affect the magnitude of corporate savings which have become an important source of supply of new capital. Although corporations invest reserves to some extent in public securities or in those of other industries, the bulk of their savings represents plant extensions and improvements; the increase in corporate savings based on rising profits is thus a factor contributing to the overdevelopment of industries momentarily prosperous, which tends to unbalance development and to aggravate the cycle. The fact that interest on long term loans is a fixed charge which does not rise with the general upswing is one of the factors responsible for the lag of costs during prosperity and contributes to unsound expansion. On the downswing the bond or mortgage interest becomes a heavy charge on industry; and the long term creditor often becomes complete owner of the business, entirely wiping out the equity of the active direct owners.

Interest as a form of property income which does not involve its recipients in direct participation in active processes of business and production is bound up in a capitalist society with group antagonisms. There is a tendency to regard as parasitic people who live from a fixed and assured income completely divorced from effort or concern with the work and life of the masses. The antagonism between the active business group and its silent partner, the outside investor of long term capital, creates the opportunity for abuses such as insiders' profits or

the shift of losses to investors; while the presence of such a party as the innocent investor, whose property must not be affected, makes regulation by public authority difficult and sometimes unfair, since most of its burden is apt to fall on the owners of the equity. At the same time the shrinking in the value of fixed incomes during prosperity and the passing of productive enterprises during depression into the hands of people who neither want nor are fit to assume the responsibility of management create social problems of far reaching significance. These social antagonisms and problems tend to become increasingly vital as industrial civilization makes more use of accumulated wealth both in providing for the satisfaction of consumers' wants and in playing the game of power in the national and international arenas.

Capital and interest are commonly regarded as peculiarly characteristic of the capitalist order. Thus while the regulation of wages by public authority and the limitation of profits by taxation were accepted as interesting experiments not vitally affecting the foundations of the capitalist system, the emergency decree of December 8, 1931, reducing interest on private loans in Germany was interpreted by many as evidence of the passing of capitalism. Yet there is no abstract reason or experimental evidence, in so far as any is available, to justify a belief that interest will disappear in a socialist or communist society. The use of the pecuniary calculus to maintain the existing stock of capital and to increase it by accumulation as well as to distribute it among the various branches of production must lead to the employment of an interest charge for the use of capital. As long as capital is merely maintained, the interest charge may be nothing more than an accounting device and the interest income received by the national authority may be returned to the producers either as a uniform reduction in the prices of all goods below cost or in some other form. But if new capital is accumulated, the presence of interest as an element of cost would mean that only a part of the total output is distributed to the population in the form of consumers' goods. In a socialist economy, however, the class living on interest income would disappear and with it also the social problems and antagonisms to which rentier incomes in a capitalist society give rise.

INTERESTS. When a number of men unite for the defense, maintenance or enhancement of any more or less enduring position or advantage which they possess alike or in common, the term interest is applied both to the group so united and to the cause which unites them. In this sense the term is most frequently used in the plural, implying either that various similar groups or advantages combine to form a coherent complex, as in the terms vested interests, moneyed interests and labor interests, or that the uniting interest is maintained against an opposing one, as in the expressions conflict of interests and balance of interests. Interests so understood usually have an economico-political character.

The importance of compact interest groups in the development and the vicissitudes of states was recognized by the great historians of antiquity in the struggles leading to the legislation of Solon and of Clisthenes, in the tenacious system of the Spartan oligarchy and later in the struggle of the orders at Rome, in the agrarian reforms of the Gracchi and in the conflicts which led to the establishment of the principate and the empire. Modern historians have seen in the clash of interests, as the conjuncture of conditions and events favored one side or another, one of the universal factors in social and political change. In one of its broadest forms it appears in the conflict of older agrarian interests with the aggressive interests associated with commerce, finance and industry. To the Marxians all history is a record of a series of clashes between various changing class interests; in the modern economic order the important conflict of interests is that between capitalist interests and those

uniting the wage earning classes. These economic interest complexes, however, are limited by competitive differences within themselves and are crossed by interests of varying potency derived from other than purely economic considerations, such as those of status, race, nation, region and religion.

The historical dominance of interest groups has at various times been challenged by conceptions of society based on individualistic doctrines, such as those of the social contract and of natural rights. In the formation of modern democratic institutions there are discernible two very different attitudes of revolt from the feudal system of established class interests; in the earlier stages the two work together, but later their latent contradiction appears. One is the democratic idea, the other the opposition of the growing interests which industrial development has stimulated, the interests of manufacturing and trading groups seizing their opportunity to dethrone the interests of the landed class. The feudal system of estates was a system of interests adjusted to the domination of property in land. The growth of other forms of property required a modification of the system but not necessarily of the principle. The "divine right of kings" was with relative ease transformed into the "divine right of freeholders." The English Revolution of 1688 was simple because it merely extended to a slowly increasing class and a slowly changing situation the old principle that the property of the country should govern it. Writers like Locke and Harrington were not revolutionary prophets but new interpreters of the old doctrine of the political role of property interests. Their social contract individualism was sharply limited by their theory that the state exists for the preservation of property. With the industrial changes of the later eighteenth century the concept of interests ceased to be formulated in the simpler terms of homogeneous "property." The new economic interests evoked by the industrial revolution revealed a different kind of struggle, which has continued with additional complications up to the present.

On the other hand, the democratic idea in its pure form was essentially opposed to the interest principle. It translated the doctrine of natural rights into the "self-evident" maxim that "all men are created equal" and drew from it the conclusions which Locke and others who had used the same language had conveniently refused to draw. This was the principle the uncompromising logic of which was enunciated by

Rousseau. It was the principle which inspired the Declaration of the Rights of Man and which in revolutionary France abolished all corporate interests within the state. It was the principle of the Declaration of Independence. It was in a later form the Benthamite principle that every man is to count as one and that the greatest happiness of the greatest number is the goal of the state.

The conflict of these two doctrines received much illumination in the course of the eighteenth and nineteenth centuries. The groups which were seeking political power were ready for the time being to enlist under the democratic banner, but when the battle was won the victory proved generally to belong to the interests represented by these groups rather than to the people as a whole. One of the most significant illustrations of the initial convergence and later divergence of the two doctrines is afforded by the events following the American Revolution. It is seen in the transition from the language of the Declaration to that of the constitution. Historians of the school of Beard have stressed the part played by economic interests in the framing of the constitution and in the struggle between the Federal and the Republican, or Jeffersonian, party. They have maintained that if Thomas Jefferson still employed the language of the Declaration after the development of the Federalist-Republican schism, it had become the language of agrarian protest against capitalist control. It need not be assumed that the ideal of democracy as enunciated by John Adams or by Jefferson had no vitality in its own right; but certainly the evidence is good that it was serviceable also, because of its vitality, to the protagonists of struggling interests. So far as the framers of the constitution are concerned, they have left no doubt as to their conception of the role of interests. They recognized that "a landed interest, a manufacturing interest, a mercantile interest, a moneyed interest with many lesser interests, grow up of necessity in civilized nations, and divide them into different classes, actuated by different sentiments and views" (Madison in *The Federalist*, no. 10). They recognized that this conflict of interests creates the problem of government and is the origin of factions or parties. But they thought that this conflict must be held in check and some balance of interests must be established in the very framework of government.

The question as to how far the state is based on group interests, whether thought of in terms

of class or of economic function or of territory, and how far on the general interest of a whole community has been a prominent issue in modern political theory. The followers of Rousseau, the school of Fichte and Hegel, have insisted on the subordination of group interests to universal state purposes. Some present day writers, such as M. P. Follett, take the same point of view (for example, in *The New State*). Others maintain that the state while deriving cohesion from interest groups is in principle above them and is ideally the impartial arbiter of their claims (Hocking, W. E., *Man and the State*). The opposite point of view is represented by such writers as Bentley, who in his *The Process of Government* claims that political issues are inevitably determined by the strength of group pressures. The adherents of the Marxian school go even further and assert that the state is essentially for the domination of one class over another; they lay stress on the solidarity of the controlling capitalist interest in the modern state. The Marxist ideal, however, points to a coming socialist state which will be essentially classless and in which the interest principle will be overthrown. The Soviet experiment has tended to give a new emphasis but also a redirection to this ideal. A somewhat different conception is held by such writers as Duguit, Benoist and Cole, who have maintained that the reorganization of the state through the representation of purely functional groups would restore to the machinery of government a reality which the "democratic" system of territorial representation lacks and would also make possible a more effective coordination of these interests within the whole. Since, however, interest groups find an important means of expression and influence through political parties and since political parties seem an inevitable condition of any democratic system, the efficacy of these proposals remains doubtful. Both the fascist and the socialist conceptions of the state assume the coercive abolition of political parties.

In economic theory the concept of interests has not been so prominent. In earlier stages this was perhaps due to the identification of economics with "political economy." The cameralists and the mercantilists took their stand on the solidarity of national economic interests. The physiocrats did work out a system of economics based on an assumption of the relative social utility of interest groups. Although Adam Smith had on occasion referred to group interests, to the classical economists they were unimportant

for the explanation of economic phenomena as compared with competitive individual interests. The historical school of economists, however, stressed the role of the group rather than that of the individual and in studying the rise and fall of institutions necessarily paid considerable attention to the conflict of interests. Socialist economists tended to stress interests even more strongly but for the most part limited their attention to the interest complexes of broadly defined social classes. The possibility of a more thoroughgoing study of the economic role of interest groups as such is suggested by the work of economists like Sombart and Veblen. Furthermore alongside the more formal studies of economic theory there have always been studies of practical economic problems and of economic institutions, in which the question of group interests has generally been accorded considerable attention.

In the theory of law interests have generally been considered as sources of conflict requiring readjustment through social agencies. From this point of view judicial decisions and the law behind them constitute a specially sanctioned process for the peaceful settlement of conflicts of interests. Law is on this ground contrasted with customary and other non-legal modes of determination of the range of interests, and the development of law is attributed to the inadequacy of these modes as interests have grown in variety and in complexity. Under such conditions custom develops too slowly to keep pace with social changes and leaves too many "areas of discretion" which are productive of social disturbance. Voluntary agencies of adjustment although they play an important part are also quite inadequate, often lacking sufficient authority to compose the issue and often, when effective, tending to disregard the interests of members of society other than those who are directly involved in the dispute. John Dickinson has said: "No fact is more important for an understanding of social processes or of the development of agencies of social control than that a conscious adjustment of interests between numerous parties cannot shape itself initially through the spontaneous action of all the interested parties, but must ordinarily result from the special efforts of some external agency . . . charged with the task of surveying the situation as a whole and devising a plan." Such an agency not only is authoritative but also can adapt its determinations to the requirements of each changing situation.

Some writers on the theory of law have given

a greater reality and concreteness to the old conception of legal rights by translating them, in the language of Ihering, into "legally protected interests." Rights, in other words, become a particular species of social interests, selected for recognition and confirmation by legislation and judicial decision. This idea has in turn led to the concept of the state as essentially an organization for the determination and adjustment of the interests operative within a society. By Krabbe, for example, the state is conceived as a regulatory power over interests, in consideration of the necessity for the continuous adjustment of these interests for the sake of practical harmony. The state, in his view, should be regarded not as the "possessor of public interests" but as a complex of agencies which administer a series of public services and of organs which generally bring into a workable system the various conflicting interests of the community. This process Krabbe speaks of as "an evaluation of interests," although in interpreting this statement the saying of Korkunov should be borne in mind that "law is the determination, morality the evaluation of interests."

In the field of sociology and social psychology the term interests has also had considerable vogue. From the beginnings of modern systematic sociology writers have sought to distinguish and classify the various aims or strivings of human beings which give rise to the varieties of social phenomena and especially of group behavior. Herbert Spencer dealt with what he called the "internal factors of social phenomena," and Lester Ward sought to classify "social forces." Ratzenhofer employed instead the term interests, being chiefly concerned to show how variant or antagonistic interests of individuals and groups explain or illustrate his theory of social conflict. This usage was adopted by Albion Small although for a different purpose and was popularized by him among American sociologists. Small offered his own classification of interests; and various other writers, such as Ross, Ellwood and Hayes, engaged in the same task. Their definitions of the term were essentially psychological. Thus Small said that "an interest is an unsatisfied capacity corresponding to an unrealized condition, and it is predisposition to such rearrangement as would tend to realize the indicated condition" (*General Sociology*, p. 433). His own list reduced itself to the following: health, wealth, sociability, knowledge, beauty, rightness. The crudity of this list is obvious; and, while it was improved upon by the other writers

referred to, the difficulty of finding a basis for classification remained. Nor was the attempt to explain social phenomena as expressions or embodiments of specific interests particularly successful. Moreover a fundamental difficulty lay in the confused application of the term at once to the subjective phenomena of motivations or desires and to objective phenomena, such as wealth. For this reason MacIver has proposed that a clear distinction should be drawn between attitudes or states of consciousness, on the one hand, and interests, or the objects toward which these states are directed, on the other. The confusions and difficulties of the interest concept have led various sociological writers to reject the term altogether and to substitute such terms as values and wishes.

If the term interests is used with this objective significance as the correlative of attitudes, the concept becomes particularly useful in the explanation of the growth and change of social organization. Under more simple conditions of society the social expression of interests was mainly through caste or class groups, age groups, kin groups, neighborhood groups and other unorganized or loosely organized solidarities. The coherence of these groups was fostered by appropriate traditions—established interpretations, as it were, of the interests or values which the groups embodied. A social class, for example, sustained its relative dominance not simply by insistence on the merits of the interests which were peculiar to its members but indirectly by the translation of these presumed merits into an ideology of prestige and social function. The attitudes thus engendered in dominant and inferior groups alike both masked the group interest and helped to perpetuate it. With the advance of civilization interests are organized in particular associations and in this way become more specialized, defined and limited. In an industrialized society with its division of labor and its opportunity for widened contacts every interest of any proportions establishes an organization for its promotion. Many quite limited and selective interests are enabled to draw their scattered adherents into personal or impersonal relations over greater areas, while the more universal interests extend correspondingly the range and the size of their organization. Thus the most marked structural distinction between a primitive and a civilized society is the paucity of specific associations in the one and their multiplicity in the other.

This definite organization of interests reacts

upon the character of the interests as well as on the modes in which they are pursued. A broad distinction may be drawn here between like and common interests. Persons have like interests in so far, for example, as each seeks a livelihood for himself. They have common interests in the degree in which they participate in a cause, as the welfare of a city or country, which indivisibly embraces them all. The two types of interest are inextricably combined in their attachment to associations. Thus the like interests which lead to economic association are reenforced by the sense of membership in a corporate unity on the success of which the attainment of these like or distributive interests depends. Moreover the association gives a greater stability to the interests which it promotes. An organized interest, especially if it assumes the form of incorporation, achieves a certain continuity in spite of the fluctuating devotion and the changing composition of the membership.

With the increase of organization the conflict of interests takes new forms, and the problem of establishing some harmony between them thrusts new tasks upon the state. There are some interests which remain localized and others which have special local aspects. But on the whole the attribution of interests to localities, the principle on which the system of representative government has been built, has diminishing significance. Moreover, inasmuch as with the development of communications many of these interests, both economic and cultural, are organized on lines that transcend the boundaries of individual states, the regulation or protection not only of such interests as may be deemed more specifically national but also of those which have inevitably a wider range introduces considerations at variance with traditional ideas of the sovereign independence of states.

International conferences reveal on a larger scale that essential problem of the reconciliation of interests which every social organization, temporary or permanent, has to face. Every organization presupposes an interest which its members all share, and its task is to find a way of reconciling with or adjusting to this wider interest the conflicting interests of its component groups or individual members. While some attention has been given to this subject, for example, by the school of M. P. Follett, much remains to be done to clarify the nature of the problem, to analyze the varying forms which it assumes and to discover methods by which the larger interest of the whole group can be most

effectively maintained against the particular interests which divide it.

INTERGOVERNMENTAL LOANS. *See* LOANS, INTERGOVERNMENTAL.

INTERLOCKING DIRECTORATES. Two corporations may be said to have interlocking directorates when one or more individuals are members of the board of directors, managers or trustees of both corporations. The practise of interlocking directorates has become increasingly widespread with the multiplication and growing complexity of corporate enterprise. At present few directors of important corporations are not directors in other concerns. The link between corporations formed by the interlocking of directors may be an important aid to management. At the same time it raises serious social problems with respect to the responsibility of directors and to the maintenance of competition.

From the purely business point of view and in terms of the interests of particular corporations the advantages of interlocking directorates

are threefold: the quality of the directorate may be raised by obtaining men of wider experience and connections or by increasing the experience and connections of the existing directorate; transactions between the two companies may be multiplied and made more profitable; and the rigors of competition between them may be reduced if not altogether eliminated and replaced by a measure of cooperation.

Since a board of directors is concerned primarily with problems of policy and control and a director's activity requires wide experience and judgment combined with extensive channels of information rather than large expenditure of time, a man with the proper qualifications can act effectively in the capacity of director for several corporations. The experience and knowledge gained in handling the problems of one corporation may redound to the benefit of other companies even in the absence of mutual business relations. Within narrow limits therefore a director may be more useful to his company if he is also a director of other important concerns. This is not the case, however, when one person holds membership on the boards of a large number of corporations; it is physically impossible for such a director to attend to his duties in all of the companies and he must perforce remain ignorant of many important activities of some of the companies. Where a director of this type is a person with a national reputation, as is all too often the case, he merely allows the use of his name to enhance the prestige of the company.

Of perhaps greater importance is the advantage which results from interlocking directorates where two or more corporations are in a position to have direct business transactions with each other. The presence of common directors can be used to gain advantage for one or both companies by insuring business on profitable terms and with the minimum of selling costs. It is not uncommon for a corporation to add to its directorate the president or another influential director of a company furnishing an important part of its raw materials or purchasing its product in large quantities. The market or source of supplies can thus be stabilized and the rigors of opposing self-interest somewhat curbed, although the relation may develop abuses in the form of preferential contracts and excessive prices. Interlocking directorates are particularly common between banks and other forms of business enterprise, since here more than in most cases a reciprocal service can

be rendered and new opportunities for profitable business created. A bank attempts to increase the number of its depositors and accredited borrowers, while an industrial or other company seeks a safe depository for its funds and an assured line of credit and banking support in times of stress. Each is a customer of the other and each supplies a service to the other. A similar dual relation may exist between a railroad and an important shipper. Through an interlocking director the railroad can protect its position against a competing carrier, while the shipper can be assured that his shipments will receive the best possible treatment; this type of interlocking has been particularly frequent between railroads and coal operators in the United States.

Finally, the rigors of competition between two companies may be reduced or eliminated through an interlocking director who serves as liaison officer between two companies, insuring that neither acts seriously to the detriment of the other and frequently bringing about a measure of common action. As the proportion of interlocking directors is increased the two concerns may act in common to the point of eliminating all competition.

Where a combination of competitors has been achieved, with the enterprises still retaining their corporate identity, the device of interlocking directors is used to unify policy and administration within the combination. Similarly the interests of a holding company in the subsidiaries under its control are represented by interlocking directors. The same device is used also by financial capitalists or large banking institutions to represent and unify their interests in the various corporations in which they own a substantial block of shares. The interlocking of directors is greatly complicated where the interests of financial capitalists are pooled through affiliation with the same banking institution, which in its turn may have independent interests in the same corporations.

From the social point of view the existence of interlocking directorates introduces two serious problems: the divided loyalty of a director of two companies which enter into business relations with each other, and the reduction or elimination of competition in a community which relies on competition as an instrument for the social control of business enterprise.

In his official capacity a director is a fiduciary and is required by law to act in the inter-

est of the owners of his corporation. A director of two companies which have business dealings with each other or other conflicts of interest is therefore placed in the anomalous position of a fiduciary with respect to both parties. The dangers inherent in this condition of divided loyalty have been recognized by the courts and certain safeguards have been developed out of the common law. In the United States "Transactions between boards having common members are regarded as jealously by the law as are personal dealings between a director and his corporation, and where the fairness of such transactions is challenged the burden is upon those who would maintain them to show their entire fairness" [*Geddes v. Anaconda Mining Co.*, 254 U. S. 590, 599 (1921)]. Where the boards of two corporations are almost identical, some courts have gone so far as to declare that agreements between them "must be deemed presumptively fraudulent unless expressly authorized or ratified by the stockholders" [*Pa. Knitting Mills Corp. v. Bayard*, 287 Pa. 216, 221 (1926)]. Under common law the burden of proof as to the fairness of intercompany transactions rests directly upon directors who are in a fiduciary relation to both parties. Even in the absence of fraud such transactions are voidable unless proved to be fair, and in some jurisdictions they may be voided at the option of either party regardless of such proof. The efficacy of these safeguards built on the common law has been greatly reduced with respect to many corporations by the so-called immunity clause in their charters; such a clause provides that no contract or transaction entered into by the corporation shall be affected by the fact that a director is connected with any party to such contract, so long as it is ratified either by directors not so connected but constituting a majority of those present at the meeting of the committee authorizing such contract or transaction or by a majority of stockholders having voting power. By these or similar provisions the duty of a director to show the fairness to both sides of a transaction in which he is an interested party would appear to be easily evaded, and the problem raised by the presence of divided loyalty would seem to be placed in much the same status which it held before the common law had been invoked. In European countries this aspect of the problem of the responsibilities of directors has been less serious than in the United States, partly because there is no charter mongering

by their political subdivisions to lower the legal restrictions on the action of directors and partly because in some countries the corporate organization tends to subdivide the functions of directors between a supervisory board with little power of action and a management board which performs the active function. Management boards are seldom interlocked; and while the supervisory boards of separate companies frequently are, the common supervisors have relatively little opportunity to affect relations between the companies.

More serious than the problem of directors' responsibility is that raised by the reduction of competition brought about by interlocking directorates, both when the concerns are doing business with each other and when they are competitors. In the first case competition is reduced indirectly by impairing the opportunity of the competitors of one of the linked companies to transact business with the other party to the arrangement. Less conspicuous and much more prevalent than the reduction of direct competition, this is perhaps the more serious of the two. No extensive investigations have been made or legislation enacted with respect to this form of "regulating" competition; yet it can be said that in a great number of cases where corporations not under common control are linked by interlocking directors, the purpose is in part to give one company (or both) an inside track over competitors in dealings with the other—to "cement their relations." This represents a very real step toward vertical integration in that buying or selling costs may be in part eliminated between the companies involved and the number of truly independent competitors may be reduced, thereby weakening the efficacy of the competitive market as a regulator of enterprise.

It is a debatable question just how far the interlocking of two otherwise competing concerns through their directorates tends to reduce competition between them. In the absence of other devices for maintaining common control a single director common to the boards of two companies is not in a position to impair seriously the competition between them unless he is either a dominant personality in one or both companies or is able to bring about actual agreements in restraint of trade between them, agreements which might have been accomplished as easily in the absence of a common director. When the number of directors in common is sufficiently large to make possible a radical re-

duction or elimination of competition, this usually indicates that two corporations are already under common control through some other device. The interlocking of directors is then a symptom and not the cause of common control and is an aid rather than an essential to the elimination of competition, which is presumably bound to follow the existence of common control.

In the United States an attempt has been made through legislation to limit interlocking directorates and prevent their interference with competition. Prior to 1914 interlocking directorates were apparently never declared illegal, but the courts in several trust dissolution cases prohibited for a period of years the interlocking of officers and directors among the dissolved corporations. The chief agitation, however, was against the use of interlocking directorates among the banks on the ground that they tended to promote a "money trust." In 1913 the congressional investigation by the Pujo committee disclosed extensive interlocking of directorates among the largest corporations, banks and insurance companies. The directors of eighteen major banks or investment banking houses (180 individuals) held 746 directorates in 134 companies with combined capitalization or resources of \$25,000,000,000. Following the popular demand which grew in part out of these disclosures the Clayton Act of 1914 contained provisions directly limiting interlocking directorates. Section 8 provided that no individual should be a director of more than one bank, banking association or trust company organized and operating under federal laws and having resources of more than \$5,000,000. An individual was also prohibited from being a director of such a bank if he were already a director of a state bank with resources of over \$5,000,000. Federal Reserve Banks were excluded from these provisions. The same section also made it unlawful for an individual to be a director of two or more corporations (other than banks and carriers) engaged in interstate commerce if at least one of them had capital and surplus of over \$1,000,000 and if the elimination of competition by agreement between them would constitute a violation of any provision of the anti-trust laws. The law, however, imposed no penalty for the violation of any of its prohibitions.

The great benefits expected to follow from the enactment of these provisions failed to materialize. Some of the larger banking houses did

immediately reduce the number of their interlocking connections. But on the whole the provisions of section 8 have been ineffective, partly because they have not been vigorously enforced and partly because dummy directors and other devices have been used to gain the same ends. Not once has the section been invoked in the courts nor has the Federal Trade Commission issued any orders to "cease and desist" under it. Interlocking directorates among financial institutions increased greatly in the post-war period; thus in 1929 the partners and directors in one investment banking house, two trust companies and three national banks, all in New York City, held over 2400 directorships in corporations with combined net assets of approximately \$74,000,000,000, equal to over 20 percent of the assets of all American corporations. The extent of interlocking among non-financial corporations is illustrated by the fact that in 1930 the directors of ten of the largest non-financial corporations held over 1850 directorships in other corporations. In both cases the large number of directorates reflects in part the increased use of holding and subsidiary companies, the directors of the parent company frequently being also directors of many subsidiaries.

More effective has been similar legislation with respect to the railroads and other carriers. By the Transportation Act of 1920 it was made unlawful for any person to hold the position of officer or director of more than one carrier unless such holdings had been authorized by the Interstate Commerce Commission. Between 1920 and 1928 the commission granted over 2500 applications, many legalizing the situation which existed at the time the act was passed, to hold such position in two or more carriers. The policy of the commission has been to refuse applications when the railroads concerned have clearly conflicting interests.

No legislation limiting the interlocking of directorates appears to have been enacted outside the United States. In other countries the public or political pressure to enforce competition has been far less strong and the problem of interlocking directorates, being one of the less important elements in reducing competition, has received little attention. In countries which have encouraged or at least not resisted the concentration of industry, such as Germany and Japan, there can be no objection to interlocking, which is extensively practised, on the score of suppression of competition. In England, the home of the competitive tradition,

interlocking directorates are frequent and have aroused some criticism but no legislative action. It has become an almost binding convention that the directors of the Bank of England should not be directors of other incorporated banks, although exceptions have been made. The charters of European corporations occasionally contain specific provisions against interlocking. In general, however, there is no opposition to interlocking directorates and they have increased greatly in Europe in recent years; among the causes are the growth of pan-European holding and finance companies and the increase in the affiliations of American and European corporations.

INTERMARRIAGE. In every society, primitive or historical, personal choice of a mate from another group is regulated by group sentiments of approval and disapproval defined by the group's vested interests and its desire to perpetuate or enhance its prestige. Current evaluations of the ranking of other groups, cultures, castes, classes, occupations, nationalities, religions and races determine the degree of encouragement or discouragement accorded a prospective marriage. Hostile attitudes toward intermarriage, which are constantly changing in their direction and intensity, range from ridicule and scorn to tabus involving ostracism or death. Correlated with heightened group self-consciousness, fostered by ethnocentric leadership and perpetuated by isolation, these attitudes act as means of insulating the group, of preventing the dissipation of its forces and of preserving its traditions against the disintegrating effect of alien influences. On the other hand, intermarriages looked upon with favor by the group are those that it believes will extend its social, economic and political power and improve its status.

Marriage functions in primitive society as a means of effecting cooperation between small isolated groups in conflict, barter and ritual; and such marriages are arranged as are thought to advance these ends. Distinctions based on property and rank when present, as, for example, on the northwest coast of America, regulate the marriage choice, as do occupational discriminations in east African society, where the blacksmith is held in low esteem. In Roman society political caste and occupational considerations determined the range of intermarriage relations. Romans had *conubium*, or legal intermarriage, with neighboring Latin groups by special grants. *Conubium* was also permitted with some peregrines who were not Roman citizens or Latins but members of political communities which had acknowledged Roman supremacy and which had been absorbed or had been granted a measure of autonomy. No *conubium* with slaves was permissible and intermarriage between patricians and plebeians became legal only after 445 B.C. A freedman could not marry his patroness or the widow or female descendant of his patron, whether the woman was of senatorial rank or not; the extreme penalty for such an offense was condemnation to the mines. Senators and their descendants were forbidden to marry freed women or men and anyone who was or whose father or mother had been engaged in the theatrical profession. Soldiers, imperial officials and tutors lost certain privileges of *conubium* during the period of their employment. When Caracalla in 212 A.D. made full Roman citizenship a common status for free subjects of the empire he increased thereby the range of territorial and racial intermarriage.

In societies where religious ritual and ceremony give significant sanction to marriage and where the interest of the group is oriented around sectarian beliefs religious differences interfere with free intermarriage. Religious sects demand unreserved loyalty and their emotional appeals for group cohesion develop attitudes of zealous exclusion in the marriage relation with members of other sects. The antagonisms against intermarriage are intensified if the religious leaders are seeking to counteract the assimilation process concomitant with religious tolerance or if there has been a tradition of embittered conflict between the religious groups involved. Economic and political factors determine and modify religious prohibitions to intermarriage, which are likewise tied up with provincialisms and national and racial consciousness.

Christianity has since its inception established impediments to marriage with those outside of the faith. On the authority of passages in the New Testament (*II Corinthians* vi: 14) and the utterances of the church fathers St. Cyprian and Tertullian the Council of Elvira (300-306) forbade Christian girls to marry "infidels, Jews, heretics or priests of the pagan rites." The Christian emperor Constantine in 339 prohibited all intermarriages between Christians and Jews and a statute of Valentinian, Theodosius and Arcadius enacted in 388 regarded such intermarriages as adulterous. The councils of Laodicea (343-381), Hippo (393), Orléans (538), Toledo (589) and Rome (743) reiterated the interdiction against the intermarriage of Christians with Jews, heretics and infidels and these prohibitions were incorporated in the Gratian collection. With the coming of the Reformation councils and synods in various parts of Europe extended these prohibitions to apply to Protestants; and popes, particularly Urban VIII, Clement XI, Benedict XIV, Pius IX and Leo XIII, inveighed against intermarriage with non-Catholics in vigorous language. The secularization of marriage laws and procedures, the increasing power of the civil authority over ecclesiastical authority in the regulation of marriage and the diminishing part played by religion in contemporary life have lessened the force of marriage impediments of the church, but they are still potent in religious communities. The revised code of canon law of 1918 reiterates the prohibition of marriages between individuals of "mixed religion" and "disparity of cult," but as a concession to the increasing laxness in the rigid enforcement of the impediments it permits such marriages if the non-Catholic party promises in writing that he will not interfere with the religious worship of the Catholic and if both parties promise that the children of both sexes will be baptized and reared in the Catholic religion. These conditions were rigidly insisted upon in 1932 in a letter issued by the church authorities who set as punishments for violations the annulment of the marriage, exclusion from participation in church activities, the denial of a church funeral and in extreme cases public excommunication.

After its secession from the church of Rome the Church of England continued to regard difference in religion as an impediment to marriage and annulled mixed marriages when made; it included among prohibited marriages those with Jew, Turk or Saracen. The Westminster Con-

fession of Faith published in 1647 declared that "such as profess the true reformed religion should not marry with infidels, Papists, or other idolaters." Ireland in 1697 passed "An act to prevent Protestants intermarrying with Papists," which provided that no Protestant woman who either possessed or was heir to any form of real property to the value of £500 should marry a Papist under the penalty of losing all her property—the act revealing economic factors underlying prohibitions against intermarriage usually concealed by the overtones of rationalization. An Irish law in 1725 made it a felony for any Papist priest or unfrocked clerk to perform a mixed marriage and a statute in 1745 threatened those who celebrated such marriages with capital punishment. A declaration of the Federal Council of Churches of Christ in America in 1932, subsequent to the statement of the Catholic church on intermarriage, asserted that "where intolerable conditions are imposed . . . persons contemplating a mixed marriage should be advised not to enter it." Some Protestant sects have prohibited intermarriage with members of other creeds on pain of expulsion; all have brought pressure to bear upon their members to marry within their religious group.

The Mohammedan law of marriage according to the Maliki school ordains that the confession of Islam by the husbands is one of the conditions of all marriages. A Moslem may not marry a woman who is an unbeliever; but on the basis of the Koran (v: 7) an exception is made of a marriage to a *kitabiyah*, a free "scriptural woman," a term which designates Christians and Jews. Such marriages although legally valid are considered "abhorrent" especially in non-Moslem countries.

Jews have also consistently looked with disfavor upon intermarriage with non-Jews. Biblical injunctions against marriage with neighboring tribes and the demand of Ezra that the Jews after their return from the Babylonian exile put aside their foreign wives were used as authority for Talmudic prohibitions against intermarriage and by Maimonides, who incorporated the prohibition in his code. Exception was made by some rabbis if the non-Jew became a proselyte; in the codification of the *Shulchan aruch* the consensus of opinion was that such marriages should be exempt from the prohibition. The Jewish synod convened in Paris by Napoleon in 1807 decided that although intermarriages between Jews and Christians in accordance with the civil code could not be solemnized by the

religious rites of Judaism they were valid and not subject to religious anathema. The declaration of the rabbinical conference in Brunswick, Germany, in 1844, that intermarriage between Jews and Christians and with the adherents of other monotheistic faiths was not forbidden if the children were reared as Jews met much hostile feeling in Jewish circles as being too assimilationist in tone. The large majority of Reform Jewish rabbis have supported the traditional orthodox opposition to intermarriage as a threat to the survival of Judaism. The food customs and ritualistic observances of orthodox Jewry concentrated in enforced or voluntary ghettos, the barriers of antisemitism and nationalistic loyalties evoked by the Zionist movement have served to maintain group cohesion; in spite, however, of the tenacious efforts of a spirited leadership the rate of intermarriage between Jews and non-Jews is increasing. Drachsler's statistics of New York City, where the Jewish population was highly concentrated, showed the ratio of intermarriage of Jews between 1908 and 1912 to be 1.17 percent, among the lowest of the intermarrying groups; the rate varied widely, however, with the country of origin, and Jews of the second generation were found to have intermarried seven times more frequently than those of the first generation.

Extensive intercontinental migration has led to intermixture of races throughout history without biological detriment (see RACE MIXTURE). Such intermixture was sometimes unimpeded by social restrictions and at other times took place in the face of discrimination. Because color is especially conspicuous it has served as a primary criterion of race in laws against racial intermarriage, but where differences in color do not reflect historical or contemporary differences in culture, religion or economic status they do not hinder intermarriage. In Mexico and in Central and South America, for example, whites, Negroes and Indians intermarry without restraint. There has been wide variance in the attitudes of the Spanish and Portuguese, themselves mixed groups, and the English conquerors toward intermarriage with native populations. Wherever garrisons of soldiers are stationed in colonial countries large mixed populations result. Racial intermarriage is common in Malaya and in the Hawaiian Islands. The eight hundred castes and subcastes and the approximately five thousand local castes of India are not exclusively racial divisions but have also arisen from occupational and sectarian differentiations. In the United

States and in the Union of South Africa, the chief arenas of race conflict, whites as a means of retaining their economic, political and social domination have legislated against racial intermarriage (*see* MISCEGENATION). Neither the laws against racial intermarriage, which are found upon the statute books of twenty-nine states, nor the intensity of the caste sentiment against it has prevented the merging of races in the United States, as is shown by Herskovits' findings that 80 percent of Negroes show traces of mixture with whites or with American Indians. The miscegenation laws have, however, prevented Negroes from obtaining the legal and property rights which the marriage contract provides. The prejudice against intermarriage with orientals on the west coast of the United States is a reflection of the prevailing social discrimination against them. Racial intermarriage has increased in Soviet Russia in the wake of full political and economic equality accorded to all racial groups.

Commercial and administrative groups in foreign countries, especially in colonial lands where they are racially distinct from the native population, do not intermarry with the latter. Governing minorities, even when of the same race and with approximately the same cultures as the governed, hold themselves aloof; and when their status is threatened by intermarriage they enact against it—the Statute of Kilkenny (1366) forbidding the English of the Pale to intermarry with the Irish is typical of such legislation. Immigrant national groups transport to their new homes the national loyalties and the Old World customs, which are suffused with heightened appeal because of the immigrants' nostalgia and their impact with a hostile culture. In their segregated ethnic communities a strong sentiment prevails against intermarriage with its disintegrating influences. These are resisted most effectively if the immigrants are massed geographically, if they have effective nationalistic leaders to foster loyalties to the traditions and language of the group through systematic propaganda and education. But even if these factors are at work, intermarriage takes place; Drachsler found an intermarriage ratio of 14 per 100 with an increase of approximately 300 percent in the second generation, an increase which ranged from 100 percent to 1000 percent among the different nationalities. The ratio of intermarriage was highest among the northern, northwestern and some central European peoples and, with the exception of the Jews and Negroes, lowest among

the Italians and the Irish. De Porte, in his study of the marriage statistics of New York state exclusive of New York City between 1916 and 1929, found that the relative number of marriages of immigrants from southern and eastern Europe in which the bride was foreign born and the groom native increased six times in a decade and that the proportion of marriages of this group in which the groom was foreign born and the bride native was in 1929 greater than the proportion among the immigrants from Canada, northwestern Europe and Germany. With the multiplicity of cultural contacts afforded by facility of communication and mobility and with the decline in immigration it has become increasingly difficult for national groups to maintain the separatist attitudes nurtured by isolation in ethnic communities. The propinquity afforded by urban and industrial life develops personal associations that do violence to the traditional stereotypes that inhibit social relations leading to marriage. Class lines which were important in marriage selection within the national and religious groups now function as the chief determining factor—the dominant economic classes seek to maintain their prestige and wealth by looking with disfavor upon marriage with persons from the lower social and economic levels. Intermarriage is also on the increase among foreign born dispersed in rural communities remote from the cohesive pressures of foreign nationalistic agencies. The fact that in the modern world marriage has become increasingly an individual matter, less dominated by parental control, has likewise accelerated intermarriage.

INTERNATIONAL ADVISERS. The practise of employing foreign advisers and experts seems to have been an outgrowth primarily of the westernizing movement which swept over a number of countries in the Orient and Near East during the nineteenth century. In the period following the establishment of the Capitulations in Turkey and of extraterritoriality in China and Japan, European advisers or controllers came more and more into prominence, being in some cases employed, notably in Japan, to reorganize the administration of justice with a view to terminating extraterritoriality.

Advisers and experts from abroad have also been frequently invited to assist in reforming financial conditions so as to remove cause for foreign intervention or annexation. Because of their inability to meet the charges on foreign loans governments have often been forced, usually under pressure from creditors, to grant aliens certain powers in connection with the collection of customs and the administration of finance. Foreign advisers or debt commissions of this type have been given varying degrees of control over the collection of revenue in Egypt, Turkey, Greece, China, Haiti, Santo Domingo, Nicaragua, Salvador, Bolivia, Liberia and Persia.

In other cases governments have employed

military advisers or missions to aid in developing their military resources and in resisting the encroachments of more powerful neighbors. An early example of this practise was the arrangement whereby Mehemet Ali of Egypt in the period after 1815 took into his service a number of officers who had formerly served with Napoleon. In 1835 the sultan of Turkey, Mahmūd II, obtained the consent of the Prussian government to employ as military adviser Captain Moltke, who later became the famous chief of the Prussian staff. Forty years later Baron von der Goltz went to Turkey, where he spent twelve years in reorganizing the Turkish army. After the Taping rebellion the Chinese government employed several Englishmen and Frenchmen in the supervision of arsenals. Within the past few years military missions have been sent to a number of countries: an Italian military mission to Ecuador and Albania, American naval missions to Brazil and Peru, an American military mission to Guatemala and British military and naval missions to a number of countries. From time to time France has had a number of military missions in Latin America and in the new states of central Europe, while Spain has organized the military and police systems of Salvador.

In addition to judicial, financial and military advisers scientific experts have been frequently engaged within recent years to instal modern methods of sanitation, agriculture, public works construction and engineering. The most extensive use of this type of foreign expert has been made by the Soviet government of Russia, which by 1930 had made contracts with nearly forty American firms and engineers whereby these concerns agreed to provide technical assistance in the construction of new plants, the installation of irrigation projects and the development of new industries. The Soviet government has likewise engaged a large number of individual foreign engineers, foremen and skilled workers.

Foreign advisers or experts have been employed during the past few years for a wide range of purposes. Brazil has employed experts in forestry, agriculture and town planning; Ecuador, in the customs, as advisers to the central bank, superintendents of banks, comptrollers general, experts in rice growing, vegetable and genetic pathologists, engineers in colonial agronomy, veterinary specialists, zoo technical experts and specialists in tropical plants; Chile, in education, health, central banking and finance; China, in the customs administration, salt gabelle coast guard, government printing bureau, legis

lative yuan, judicial yuan, Ministry of Finance, Ministry of Communications, Ministry of Railways, Ministry of Industry, Ministry of Interior, Ministry of Military Affairs, National Reconstruction Commission and River Conservancy Commission; Persia, as wireless experts, financial advisers, directors of national bank, administrators general of customs, technical health advisers, directors of antiquities, road and highway engineers, tea experts, agricultural and veterinarian experts, directors of printing plant and experts in the foreign office.

International advisers may be classified at present as of two main types. The first is the consultant who visits a country, studies the difficulties concerning which his advice is sought, prescribes a remedy and returns home, the responsibility for carrying into effect his proposals being left to the local government. Largely because debtor countries have often found it impossible to obtain foreign loans without first putting their house in order, consultants of this type have been concerned in the main with financial problems. Within recent years invitations to study the local financial systems have been issued by many countries to a number of well known authorities, such as Charles Rist of France, Sir Otto Niemeyer of England and E. W. Kemmerer of the United States, who has performed the services of a "money doctor" for about twelve governments. Usually the recommendations of the Kemmerer financial missions have related to the establishment of the gold exchange standard, the creation of a central bank of issue, the establishment of budget laws and fiscal control systems and the enactment of new tax measures. More striking examples of this type of financial expert were the members of the Dawes committee of 1924 and of the Young committee of 1929, both of which were composed of a large number of financial and business experts from various countries, who diagnosed the financial troubles of Germany primarily with a view to securing reparation payments.

As a result of the recommendations of consulting advisers a number of countries, particularly in Latin America, have carried out reforms which apparently have led to improvements in administration and made it possible to secure foreign loans. The practise is criticized in many quarters, however, on the ground that governments employ foreign financial advisers merely to obtain loans with no real intention of carrying out the promised reforms. Yet even in

such situations responsibility would seem to fall more logically upon the foreign bankers and the borrowing government than on the adviser who acts in good faith. It is also contended that no government can hope successfully to adopt the intricate financial methods of the leading countries merely as a result of recommendations by visiting advisers and that modern financial methods can be developed only as part of the institutional growth of a country. On the other hand, foreign advice in a difficult financial situation may have considerable psychological and political value, as was evidenced in the work of the Dawes reparations committee of 1924.

The second type of adviser or expert, the one who remains in a foreign country for a period of years either advising in regard to or actively participating in administration, is in many cases appointed as a result of the recommendations of the consulting type of expert. Many of the laws drafted by the Kemmerer missions provide for the appointment of a permanent body of foreign banking or financial experts. The Dawes committee recommended the appointment of three foreign commissioners to supervise the "controlled revenues," the railways and banks of Germany as well as an agent general of reparations and other foreign officials—constituting an organization which was set up by the agreements signed at the London conference of 1924 and which continued in operation until the adoption of the Young plan.

It is difficult to distinguish between those foreigners who serve merely as advisers and those who actually assume responsibility for administration. The tendency generally is for an adviser to become, at least in extremely backward countries, an administrator. Many controversies have arisen between governments and advisers over the scope of the functions of the latter. In those instances where a government employs an adviser merely to secure a foreign loan or to satisfy the political demands of a great power it usually pays little attention to his recommendations unless he is the official representative of an outside government, as in the case of the American financial advisers to Haiti and Liberia. Even where a government genuinely wishes to make progress, the role of an adviser is not easy. As a rule his powers are limited to persuasion, and whether he succeeds in bringing about reforms depends not only upon his technical knowledge but upon his personality and ability as an educator. A successful ad-

viser must be not only an expert but also a teacher and statesman endowed with infinite patience.

Many countries in the process of obtaining independence realize the desirability of foreign advisers. Egypt employs financial and judicial advisers from Great Britain, and it is not unlikely that Iraq after the recognition of its independence and admission into the League will employ a number of British advisers. It is also probable that India and the Philippines upon becoming self-governing or independent will wish for the same reason to make use of outside aid. On the other hand, growing nationalism and self-confidence often lead a country to reduce the authority and number of foreign advisers. The Nanking government of China, for example, has increased the Chinese personnel in the customs, salt gabelle and postal services.

Advisers have often been used by the great powers as a means of establishing control over or even of governing backward areas. Great Britain came to rule Egypt through a system of British advisers responsible to the British consul general at Cairo. Native rulers in Tunis and Morocco are obliged to take the advice of French residents general and other officials. In a number of areas in Africa, such as Uganda and Nigeria, the British government follows a policy of indirect rule in which responsibility is imposed upon native states, which are, however, subject to constant check by British administrators who are in a sense advisers. In the native states of India British advisers are also to be found, although they exercise less authority here than in the native states of Africa.

The extent to which the adviser may become an instrument of imperialism can be illustrated by frequent historical examples. In 1897 Russia and England engaged in a struggle over the question whether an Englishman should be financial adviser to the king of Korea. Neither government won this struggle, for in a protocol of 1904 Korea agreed to accept a Japanese financial and diplomatic adviser, which ultimately led to Korea's absorption by Japan. In the famous twenty-one demands of 1915 Japan asked that China employ Japanese advisers in political, military and economic affairs. Communism also advances its cause by the system of advisers. Thus M. Borodin became extremely influential in the Kuomintang government of China in the three years from 1924 to 1926. Sometimes governments have attempted to compromise these

rivalries over advisers by the sphere of influence system. In the unratified agreement of 1920 France, Great Britain and Italy promised that in their respective Turkish spheres France and Italy should have a "preferential" claim to supply advisers if the Turkish government desired assistance.

In an effort to eliminate the military influence of Germany the Treaty of Versailles (art. 179) provided that Germany should not send to any foreign country any military mission and should take measures to prevent German nationals from leaving her territory to become enrolled in the military forces of any foreign power. The Allied and Associated Powers agreed moreover not to employ any German military experts. Despite these provisions General Hans Kundt, a German military expert, was chief of staff in Bolivia until the 1930 revolution, while German experts have advised the Nanking government of China in military affairs.

There are a number of cases where a government torn between the demands of two rival powers will turn as a measure of protection to a supposedly neutral country for advisers. Thus Siam, which at one time feared the encroachments of Great Britain and France, has employed a number of American advisers since 1903. Fearing absorption by Russia and England the government of Persia in 1910 asked the State Department of the United States to recommend an adviser to assist in the reformation of its finances. The department responded with a list of possible candidates, from which the Persian government selected Morgan Shuster. Russia, however, sent an ultimatum to Persia, as a result of which Shuster resigned. Following an abortive agreement with England in 1919, which apparently would have resulted in a British protectorate, the Persian government again turned to the United States, this time employing A. C. Millspaugh, who had been a State Department official, as administrator general of finances. In 1927 he resigned and was succeeded by German and Swiss experts, all of whom were made subject to the Persian minister of finance.

Within its own sphere of influence the United States has employed advisers for political purposes perhaps to as great an extent as any other power. As part of the policy of "dollar diplomacy" the United States in 1907 concluded a treaty with the Dominican Republic which provided that the president of the United States should appoint a general receiver of Dominican customs and his assistants, who would receive

from the United States "such protection as it may find to be requisite for the performance of their duties." In 1915 the United States concluded a more far reaching treaty with Haiti which authorized the president of the United States to nominate a general receiver and financial adviser as well as officers to organize a constabulary. By virtue of the authority supposedly derived from this treaty the United States sent about two hundred Americans to take up positions in the Haitian administration, which, nominally at least, continued to be headed by a native president and cabinet. American financial advisers have also been nominated under authority of loan contracts between the foreign government concerned and American bankers. Thus in 1911 the Nicaraguan government signed a contract authorizing the appointment of an American collector of customs. In 1926 the Liberian government entered into a similar contract with the so-called Finance Corporation formed by Harvey S. Firestone whereby the State Department of the United States undertook directly or indirectly to nominate seven Americans to act in an expert or advisory capacity for the Liberian government. Within recent years American financial experts have been employed, often following consultations with the State Department, by the governments of Colombia, Cuba, Guatemala, Honduras, Panama, Peru, Bolivia, China, Ecuador, Hungary, Mexico, Paraguay and Poland. In an act of May 19, 1926, Congress authorized the president of the United States to detail officers and enlisted men to assist Latin American governments in military and naval matters. Today American officers are in command of the Haitian and Nicaraguan constabularies.

Because of the political implications of the national adviser and because his responsibility is often ill defined, there are many theoretical advantages in favor of the international adviser; that is, an expert selected to serve a foreign country by some disinterested international organization, such as the council or technical organizations of the League of Nations. The Provisional Finance Committee of the League has stated these advantages as follows: "Some countries which would be unwilling on grounds of prestige, to apply for advisers to particular governments, may be willing and anxious to utilize the services of an international and impartial body like the League of Nations for this purpose, and in view of the fact that the financial administration of certain States

is at the present very critical time in the hands of relatively inexperienced officers, we venture to think that an experiment in the direction indicated may be fruitful of good results." In 1922 the Albanian government asked the League Council to assist it in selecting a number of advisers, and the Council nominated J. D. Hunger of Holland as financial adviser. The Albanian government, however, largely because the League was unable to provide it with a loan soon repudiated his contract and turned to Italy, which has established a predominant influence over Albania by means of Italian loans and Italian advisers—a form of control which is the object of suspicion in the Balkans and throughout Europe.

As part of the League reconstruction plans for Austria and Hungary the League Council appointed a commissioner general to each country and also certain other foreign experts. The League health and transit organizations as well as the International Labor Office have likewise performed important services in advising governments. If the League of Nations grows in authority, the time may come when all advisers to needy governments will be appointed by and made responsible to international authority.

INTERNATIONAL AGREEMENTS. *See* AGREEMENTS, INTERNATIONAL.

INTERNATIONAL ARBITRATION. *See* ARBITRATION, INTERNATIONAL.

INTERNATIONAL, COMMUNIST. *See* COMMUNIST PARTIES.

INTERNATIONAL FINANCE comprises the network of transactions and institutions connected with the transfer of money or of credit from one country to another. The pecuniary claims of one country against another are settled to a very large extent by bringing into play the obligations of the creditor country to a number of other countries which in their turn have to meet the claims of the debtor country. The balance remaining after such international clearing must, however, be paid by the shipment of money (gold bullion) or postponed through some form of credit.

The transfers of money or of credit by one country to another may be described as tributes in the technical sense of the term and advances. Tributes represent unilateral payments of primarily political origin. They include contributions drawn by a mother country from its colonies; subventions paid by a metropolis to its dependencies; military subsidies paid by one government to another; war indemnities, such as the reparations payments; or obligations arising from a former state of dependency, such as the Egyptian tribute of £720,000 per annum formerly payable to Turkey. Advances represent loans granted by one country to another or investments made by one country in the economic activities of the other. Advances give rise to two international financial movements: at first from the lending and investing country to the borrowing and capital importing country and later, with

the beginning of payment of the service on loans and of the return on investments, in the opposite direction.

Several types of international advances may be distinguished according to the character of the parties to the transaction. In the case of intergovernmental loans the creditor and the debtor are both governments. Such loans played an important part during the World War, when the British government and later the United States government advanced funds to their allies. The guaranty by a government of a loan issued in a money market under its jurisdiction by a foreign government resembles in many ways an intergovernmental loan; the subject of the advance in this case is not money but the credit of the government with private lenders. Examples of this type are the Russian government loan made by English and Dutch bankers in 1820; colonial or quasi-colonial issues, like the Sudan loan of 1919; and the Austrian League of Nations loan of 1922. The most frequent type of international government loan in modern times is the borrowing from private citizens of foreign countries, particularly through the public flotation of government securities in foreign money markets. On the other hand, the most unusual form of international government finance is government ownership of property in foreign lands, such as the ownership of railroad lines in the United States by the Canadian government or the control of Suez Canal shares by the British government, or the grant of government credits to private concerns established abroad; government credits are rarely given to companies domiciled in foreign lands except to those operating in colonies, spheres of interest or regions approaching colonial status. The largest share of the total volume of international financial transactions, however, does not concern governments either as debtors or as creditors. Such transactions involve private citizens or corporations of one country lending to or investing in private enterprises in another country. They include long term loans and permanent investments as well as the great bulk of short term international financing, the total of which is enormous.

International financial relations are meant to be either temporary or permanent. The direct ownership of property in one country by persons or corporations of another country constitutes a permanent financial link. The international relationship created by foreign holdings of stocks, bonds and mortgages may be severed

more easily; when the stock exchanges function regularly and securities have an international market, the lines dividing permanent and temporary investments are rather blurred. Temporary financial relations typically arise in the course of trade between two countries. Acceptances and revolving credit are bound to be self-liquidating and short lived, as are also deposits of funds in foreign banks recallable on demand or at short notice and holdings of foreign bills of exchange. The volume of short term international credit has grown immensely in recent years; thus the net commitments of the London market alone were about £245,000,000 in March, 1931. But this is due not so much to a stupendous growth of international trade or of the need for financing it as to the hesitation of the capital exporters to invest for long terms. Since the World War the owners of capital have consistently preferred the comparatively lower yield that goes with the opportunity of withdrawal at a moment's notice to the risk involved in permanent investments at a time when stock markets do not function properly and governments are not always willing to respect contractual obligations.

Under normal conditions, when the fluctuations of foreign exchange rates are confined to a very narrow range, the international movement of short term funds is governed completely by the relationship obtaining between money rates in the different money markets: if rates in one market decline relatively to the rates prevailing elsewhere, funds will be exported; if rates rise, funds will be imported. The advances made through this mechanism by one market to another may be regarded therefore as equilibrium loans. Another type of short or medium term loan, characteristic of the post-war era, is the currency or stabilization loan advanced by one central bank to another with the object of enabling the latter to maintain or to reestablish the stability of its exchanges. From the point of view of economic function most of the advances made to private citizens or corporations and the advances made to governments for productive purposes must be regarded as development loans: they enable the borrowing country to develop its resources at a much quicker pace and at much smaller capital costs than would be possible were they to rely entirely on their own savings.

Development loans obviously enable the creditor country to draw a higher rate of interest—they raise the income of its rentier class and provide additional profits for its bankers. They

also open up new markets for its industries, at first because the proceeds of such loans are spent in buying industrial equipment from the creditor country and later because development loans provide the inhabitants of the borrowing country with new or enlarged incomes, which can be spent on purchasing imports. The widening of the markets for the industries of the creditor country raises the wages of its laborers and the profits of its entrepreneurs. Again, the development of new countries by means of such loans assures an increased supply of foodstuffs and raw materials, upon which the creditor country is enabled to draw by the return on its capital exports. The benefit to the debtor countries may be much greater. The economic transformation of a stationary non-capitalistic system in countries inhabited by primitive peoples cannot proceed without advances from abroad, while new countries settled by white immigrants need foreign capital to make the nation an efficient economic unit. Debtor countries have often artificially accelerated the process of their industrial development by raising tariff barriers against manufactured goods, thus forcing their creditors to finance not only non-competitive industries, such as railways, but also manufacturing establishments competing with the industries of the creditor country. From a purely economic point of view the result is probably the greatest misdirection of capital in which the modern world has indulged—the output of existing plants in the creditor country shrinks while new plants which represent considerable investments and which have at best a limited market enter an already crowded field.

The acquisition of property or claims to income by aliens has given rise to grave political problems, especially where the social traditions and legal conceptions of the debtor countries differ from those of the western world. The status of alien residents in such countries is regulated by special arrangements, which usually include the right of the foreign trading community to be subject to its own law and its own law courts as far as the transactions among its own members are concerned, while its transactions with the natives are subject to the jurisdiction of special tribunals and special courts. The abolition of these privileges, very objectionable to the native population, occurs only after the establishment of trustworthy native tribunals which can be charged with the application of native codes framed after western patterns.

Alien property is less secure than native even in countries of the same social and economic civilization. While it is fairly easy to make contracts fit into different systems of law, the impartiality of courts toward strangers is by no means everywhere assured. Where the creditor is a foreigner, national prejudice is likely to be aroused in times of stress; this occurred, for example, in 1931 and 1932 when the City of London was denounced by some labor leaders in New South Wales as the embodiment of rapacious capitalism. National prejudice of this sort, sometimes encouraged by special legislation, has often excluded foreigners from buying land or stock of important corporations with full voting privileges. It disregards the obvious fact that it is the creditors rather than the debtors who face serious dangers by placing their capital within the jurisdiction of foreign law courts and the grasp of foreign governments. The wholesale confiscation of foreign property during the World War has shown how serious this risk is.

The political aspects of foreign loans come to the fore when the debtor is unable to pay. The incapacity of individual concerns abroad to fulfil their obligations differs from individual bankruptcies at home only in so far as it may involve a clash of different legal systems; but where the debtors are large concerns of national importance or where numerous corporations break down simultaneously under the stress of an economic crisis, the possibility of their passing into the hands of foreign bondholders and the measures taken by the government of the debtor country to relieve the critical conditions of business raise political problems of international importance. Moreover the fear of bankruptcy may lead to the withdrawal of foreign short term credits and the sale by foreigners of long term investments at sacrifice prices; under such circumstances the currency system of the debtor country may be easily deranged, as very nearly happened in Germany in the summer of 1931. On the other hand, currency disturbances caused by faulty government finance may prevent even solvent debtors from fulfilling obligations contracted in foreign money. In either case resort is sometimes had to wholesale moratoria, which extend to foreign loans and undermine the confidence of the foreign creditor.

Far more serious friction is caused by the bankruptcy of foreign governments. Only in exceptional instances does it take the form of complete repudiation of debts; of this Russia is the classic example. More often a government

withholds for a limited period interest due on its obligations or funds it into another interest bearing obligation; sometimes it resorts to a forced conversion of its debt at a lower interest rate, a reduction of interest which may be achieved almost as effectively by the imposition of a coupon tax. Where government bonds held by foreign investors are in terms of the domestic currency, a generous inflation may materially reduce the public debt without an acknowledged breach of the government's legal obligations. Defaulting governments can rarely be sued in their own courts; and even if judgment were given against them, foreign creditors could hardly make use of it as long as they could not sell government property or attach government revenues. Although governments scarcely ever assume responsibility for the investments of their nationals in foreign countries they are often made to intervene when frictions connected with such investments lead to loss of life or to "denial of justice." In the case of comparatively weak states creditor countries have often employed naval demonstrations, occupation of ports or some form of blockade; even since the general recognition of the Calvo and Drago doctrines governments have used diplomatic pressure and occasionally direct military intervention. In the case of older and stronger states such measures are not available. The foreign creditor is then protected merely by the hesitation of the government to impair its credit standing. While the capital markets of the world are not thoroughly organized and while the various defense associations of foreign bondholders do not cooperate in every case, few governments are able completely to rid themselves of their old obligations; when they need new loans they must settle with their old creditors, although Russia seems to have succeeded in getting camouflaged import credits without compensating its old creditors.

The dominant fact, lost to a superficial view in the mazes of international finance, is that wealth and especially moneyed wealth is not merely a source of income but an embodiment of economic power. In national affairs the money power is under the sway of the national government, although in some cases it openly or secretly controls the government. In international affairs political and financial power are in separate hands; hence the variety of possible combinations, which ranges from sincere cooperation to bitter animosity.

Theoretically the foreign money lenders,

whether as individuals or as a body are interested in obtaining a higher personal income rather than in political domination. While their principal is safe and the promised return on their investment is secure their attitude remains passive; but passivity gives way to panic, which affects adversely general financial and business conditions, whenever either the principal or the return on the foreign investment appears to be in danger. As long as loans to foreign governments were made directly by the owners of the capital, the power which the investor could exercise was very limited; his position was vulnerable because the refusal of the debtor government to pay spelled his own bankruptcy. But under modern conditions the money power is wielded not so much by the owners of the money as by the intermediaries to whom they have entrusted it—the great banks and issue houses. With the development of the modern stock exchanges the amount of money available to the great lending institutions has increased enormously; and their influence has grown correspondingly, particularly since their own financial strength is no longer completely at the mercy of foreign governments. They have been able to evolve and to enforce a technically complete system for safeguarding the interest of the foreign creditors. States whose solvency or whose willingness to pay is doubtful have been forced to pledge certain revenues for the service of a loan; these revenues are paid in a separate account under the control of the creditor and supply sufficient surplus reserves to meet all possible contingencies. In other cases the administration of certain monopolies, as the tobacco monopoly in Turkey or the various safety match monopolies granted to Kreuger, are handed over to the creditors, with the double object of increasing the yield by efficient administration and of giving them complete security. The system of creditor protection reached perfection in Turkey before the World War and Egypt under Lord Cromer. The governments of these countries had contracted huge loans and squandered their proceeds with the result that the state budget was permanently unbalanced. The investment of the creditors could be saved only by the creation of a creditors' administration, on which the different creditor countries were represented proportionately to their commitments. It reorganized the country's finances and especially the administration of the revenues which were allotted to the debt service. The native government was outwardly maintained,

but the creditor countries insisted on the introduction of skilled advisers in all of its branches. After the war the principal financial features of these schemes were introduced in Austria and Hungary under the auspices of the League of Nations. In Germany this was done under the Dawes plan and some traces of it were retained even under the Young plan.

While foreign investors are interested mainly in the security of their claims, the governments of creditor countries have often used the financial power vested in their money markets for political purposes. Loans were offered and in some cases even obtruded on less organized nations for military or political concessions. Financial control was resorted to not merely for the purpose of rehabilitating the country and securing the creditors' rights but for getting control over its administration without having openly to assume political responsibility. In many cases there has been a quick transition from a loan made to a native ruler, originating in the wasteful splendor of his court and in the greed of an unscrupulous financier, to reorganization by a creditors' council, which in its turn has led to a protectorate that has easily developed into control equivalent to political annexation. In countries where the rivalry of the various nations made direct annexation virtually impossible, a creditors' council sometimes provided a useful form of international financial administration, which guaranteed financial security and a certain amount of economic progress without political control. International finance was thus made to provide a capitalistic substitute for political colonization and territorial imperialism.

In some cases international finance enabled native governments to develop the resources of their countries and greatly to improve their economic status. For the promise of a share of profits foreign financial interests were allowed to form corporations for the exploitation of railways, mines, oil fields, plantations and public utility services. Such corporations were sometimes strong enough to control the native governments. The De Beers company in Cape Colony in South Africa was for a long time in this position; and the connections of foreign finance with the Díaz regime in Mexico were intimate and unbreakable. While the profits of the foreign concession holders were accumulated in many cases at the expense of the native workers, the upper and the middle class of the backward countries participated in this newly created

wealth. Even where these corporations acted wisely, friction was bound to arise with the spread of modern democratic ideas. The friction often assumed the form of a conflict between labor and capital in countries which did not appear sufficiently advanced for such a class struggle; in fact it was a revolt of more or less backward native populations, wedded to old traditions, against industrialism, which was forced upon them by capitalistic development impersonated by foreign financial exploiters. In this case too financial power has been wielded not by the owners of the money but by people to whom it was entrusted, although the connection of the large shareholders with the administration of the companies is naturally closer than that of the bondholders with the issue houses.

The general adoption of the gold standard and since the World War the popularity of the gold exchange standard have given rise to new powerful influences in international finance. The central banks, which in most countries are supposed to be independent of the government although everywhere their connection with their respective treasuries is very close, are in a position to exert considerable influence on the international distribution of gold and thus to contract or to expand the base of the credit pyramid not only in their own country but also abroad. Ultimately of course the international distribution of monetary gold stocks is determined by the distribution of the world's income among the various nations, as effected through the adjustments in the balance of payments; but in the short run central banks can control the volume of short term loans, regulate the financing and the actual flow of commodities and affect thereby the movement of gold in and out of the country. The degree of control over credit which the central bank enjoys in its own country varies; more important in this connection is the fact that the power to affect credit abroad is vested only in central banks of the large creditor countries—at present the United States, France and England. The debtor countries are more or less dependent on them for the financing of their imports as well as for the maintenance or the restoration of the stability of their currencies. It is, however, only in normal times, when traders' decisions are decisively affected by small differences in profits, that the central banks might be considered powerful. In critical times, when confidence is waning and price fluctuations are apt to be large and frequent, the central bank may not be

able to enforce its policy. The declaration of a change in its discount rates no longer works automatically; in fact the raising of rates may be interpreted as a storm sign and may lead to huge withdrawals of foreign short term funds, with the result that an unwanted severe contraction of credit takes place if the gold standard is retained or a complete dislocation of the foreign exchanges sets in if it becomes clear that the reserves are not large enough to withstand the drain. The events of post-war financial history have shown that even strong central banks, like the Bank of England, are at the mercy of their countries' foreign creditors when the crisis is sufficiently acute.

Because central banks are powerless in times of crisis, they have been unable to control the flow of credit and the international distribution of gold by that close cooperation upon which they have embarked since the war. The need for organized and explicit cooperation after the war was created by the lack of recognized international leadership among central banks. It was assumed at the same time that the power of a central bank within its own country could be enhanced by assurance of cooperation from abroad. The cooperation of central banks was expected to provide a type of international financial control which would impose sane, healthy and reasonable international policies on the foolish political passions of nations. Some such hopes were cherished when the project of a "world bank" was being grafted on what was intended originally as a clearing house for reparations payments; it was to be a powerful international financial agency, acting for the best of mankind in a purely rational way and unhampered by political considerations. The actual creation, the Bank for International Settlements, has justified these hopes neither by its constitution nor by its performance. Its charter providing rather limited powers cannot be enlarged without the consent of every government concerned; and its activities, although highly beneficial in a modest way, can scarcely be interpreted as imposing the wisdom of international finance on the folly of national politics.

INTERNATIONAL LABOR ORGANIZATION. The International Labor Organization represents an attempt to integrate under governmental auspices the various aspects of an international labor movement which had been developing for over a century. In the early days of industrialism Robert Owen and other philanthropic employers, having become convinced that protective labor legislation although increasingly urgent could not be effective under the prevailing system of unrestricted national competition, proposed international regulation. Similar ideals and programs continued sporadically throughout the nineteenth century to exert influence in a few quarters; but the movement did not progress beyond the stage of resolutions, such as those drawn up by the Berlin Labor Conference of 1889. The founding of the International Association for Labor Legislation at Paris in 1900 marked, however, the beginning of a more coherent program. Under its auspices the Berne conferences of 1905 and 1906 formulated the first multilateral labor conventions, which

prohibited night work for women and the use of white phosphorus in match manufacture. In the years preceding the outbreak of the World War the association gained in prestige, coordinating and expanding its program of standardization and reform of labor legislation.

The war, which frustrated the preliminary work of the Berne Conference of 1913, acted as an unprecedented stimulus to the international labor movement; as a result of conferences between trade union organizations of the various countries it emerged from the war with a clearly formulated program of demands. Impelled by motives of gratitude for labor's wartime sacrifices as well as by an enlightened sense of precaution against the threat of Bolshevism, the peace conference of 1919 shortly after assembling in Paris appointed a Commission on International Labor Legislation, to which was delegated the task of outlining an international labor organization and a world labor charter. The report of the commission, based primarily on a draft submitted by the British delegation and couched in the current idealistic terms of social justice and universal peace, was accepted promptly and with but slight modification. In view of the general labor unrest it was decided to set the organization in motion as quickly as possible, and the first conference was held in Washington, D. C., in October, 1919, before the peace treaties came into effect.

While in 1920 the labor conference was held in Genoa, those in subsequent years have been held in Geneva, where the contacts of the Labor Organization with the League of Nations have been numerous and intimate, although it has constantly maintained its autonomous status. A state which is a member of the League is automatically a member of the affiliated organization; a state may, however, withdraw from the League and still maintain its standing in the more specialized body, as did Brazil; Germany and Austria, on the other hand, were admitted in 1919 prior to their admission to the League. In order that the decisions of the annual conference may conform to a reasonable degree with the anticipated attitudes of the various governments which will be asked to ratify and incorporate them into national legislation, and to satisfy the demands of the trade unions, a system of representation is followed whereby two government delegates, one from the most representative association of employers in the country and one from the corresponding association of workers, are appointed by the governments. In contrast

with orthodox international practise each of the four delegates votes individually, and the voting alignments have shown a marked tendency to follow group rather than national loyalties. The final decisions of the conference, which require a two-thirds majority vote and are arrived at in the greater number of cases by a process of compromise, are of two types. The more formal draft convention must be submitted within a limited period to the competent ratifying authority of each member. A state, once it has ratified such a convention and deposited its ratification with the secretary general of the League of Nations, accords the convention treaty status and theoretically exposes itself in case of violation to measures of control, such as investigation by the Governing Body or the Permanent Court of International Justice, and even to concerted economic pressure. The second, less stringent type is the recommendation, which does not require ratification, although information concerning its application must likewise be deposited with the secretary general of the League. In federal states where social legislation falls within the jurisdiction of the smaller units the draft conventions may be treated as recommendations. After trying several unsatisfactory systems of adopting conventions and recommendations the present "double discussion" procedure was evolved and first employed in 1927 and later revised in 1929. Under this system a first conference devotes itself to a discussion of national law and practise and may adopt draft conclusions. During the course of the ensuing year questionnaires covering the points raised in the draft conclusions are forwarded to the governments of all member states. When the conference reassembles the following year it is presented with proposed draft conventions or recommendations which represent an average position based on the replies to the questionnaire. The conference may then finally adopt a draft convention or a recommendation.

The small group of twenty-four representatives, known as the Governing Body, meets at least four times a year. Because of the importance of this body the determination of its membership has been a source of contention since the early years of the organization. As in the conference, the governmental representation is equal to that of employers and workers combined. Eight of these government representatives are permanently apportioned, according to the terms of the peace treaties, to the countries of chief industrial importance. The original selection of criteria for

determining this importance was contested by several excluded states; in 1922 an investigation carried out under the auspices of the Council of the League awarded these seats to Belgium, Canada, France, Germany, Great Britain, Italy, India and Japan. The other four government seats as well as the twelve functional seats, which are divided equally between employers and workers, are held for three years and are filled by the vote of the corresponding groups of representatives in the conference. Efforts of certain outlying states to counteract the predominantly European cast of the Governing Body by the introduction of geographical ratios have so far proved unsuccessful. This group of twenty-four, often working through small committees which contain the three types of representation, controls to a large degree the finances of the organization, draws up the budget, which is passed by the League Assembly, participates in the activities of the League in so far as they involve the conditions of labor and establishes the agenda of the annual conference. Moreover it works in closest cooperation with the director and deputy director of the International Labor Office.

The office collects and publishes information on the problems of industry and labor and conducts exhaustive research in collaboration with permanent or ad hoc committees of specialists and experts in the preparation of conventions and recommendations. Its well known investigations concerning social insurance, wages, production and conditions of work in coal mines are but the more notable examples of research which it is conducting in varied fields of industry, commerce, agriculture and migration. Its library is becoming an outstanding research center for specific labor problems.

While Americans took an active part in framing the labor section of the Versailles Treaty—Samuel Gompers was president of the peace conference Commission for International Labor Legislation—the United States is not a member and the American Federation of Labor has shown only moderate interest in the organization. Failing direct collaboration with the "most representative" American employers' and workers' organizations, important unofficial collaboration on industrial relations has developed. Americans have on occasion been connected with the International Labor Office and at various times have participated in the investigations of technical committees and conferences. Although the Soviet Union, the only other outstanding non-member, regards both the organization and the

League as appendages of western capitalism, the Soviets have for several years exchanged documents and scientific information with the office. The attitude of the great trade union organizations, such as the International Federation of Trade Unions with headquarters at Berlin, is friendly, although their representatives in the conference have had some difficulty in cooperating with members of the Christian trade unions. They have moreover because of unwillingness to recognize the Italian Fascist corporations made repeated attempts since 1922 to have the credentials of the Italian workers' delegate rejected by the conference. While the employers are often openly skeptical of the value of the organization, only the shipowners (the employers' representatives at maritime sessions of the conference) have gone so far as occasionally to refuse cooperation or to withdraw from the conference, as they did for a few days during the maritime session of 1929.

The thirty-one draft conventions and thirty-nine recommendations adopted by the conference during the period from 1919 to 1931 represent a definite trend toward the international codification of labor law. A cardinal objective of the Labor Organization is freedom of association as a preliminary to trade unionism and collective agreements. An attempt to frame a convention on this subject in 1927 failed because it did not go far enough to satisfy the workers' group, but the principle has been applied on several occasions in connection with the nomination of the workers' delegates to the conference. An equally dominant objective is the regulation of the hours of labor. The Washington hours convention of 1919 which provides for the eight-hour day and forty-eight-hour week in industry has, however, been ratified with extreme caution. The other conventions and recommendations include protective regulation of the conditions of labor among agricultural and industrial employees, women and children, forced native laborers, foreign workers, seamen, coal miners and others as well as provision for certain kinds of social insurance, industrial hygiene and inspection, the prevention of industrial accidents and the development of measures to combat unemployment.

Most of the constitutional difficulties of the organization have been solved. The procedure of preparation and adoption of conventions has been greatly improved and the technique of revising conventions after their adoption has been formulated and tried. Three broad problems

now face the organization: the elaboration of its code of labor law, the extension of the international network of ratifications and the effective application of conventions when ratified. The annual conferences assure a gradual evolution of international labor legislation which will fill the remaining gaps in the program outlined by the peace treaties and adjust national labor legislation to future economic change.

It is difficult to estimate the actual effect of the organization's work on national legislation. The gradual accumulation of ratifications (454 had been deposited up to March, 1932) will no doubt continue and with a return of normal economic conditions will be greatly accelerated. But the fact that varying degrees of industrialism in the member countries and their already existing standards must be taken into account makes it impossible to gauge progress solely by the number of ratifications. Nor have ratifications in the less industrialized countries always meant elevation in the standard of living of the workers. On the other hand, members refusing to ratify on technical grounds have often maintained a relatively higher level of life for workers than ratifying governments. As ratifications accumulate and take effect, these inequalities may tend to become adjusted and the fear on the part of industrially advanced states of unfair competition from industrially undeveloped countries will probably diminish, thus removing a significant obstacle in the way of more rapid progress.

Perhaps the most important single constitutional development in the organization is the application of expert observation to the annual reports which governments are obligated to submit under article 408 on the enforcement of ratified conventions. For several years this procedure has been bringing to light the failure of certain states clearly to conform their national legislation with ratified conventions, and gradual improvement may be observed.

The International Labor Organization has attained far more than its enemies conceded in its early years; but it has achieved much less than its friends thought possible. From the governmental standpoint there is little doubt of permanent support. Regardless of the conflict of interests sometimes observable in the debates between employers and workers in the conference, Governing Body and committees, their collaboration seems to be a stable factor in modern international life.

(Levine, Louis), *Labor and Internationalism* (New York 1929); International Labour Organization, *The First Decade* (London 1931).

INTERNATIONAL LAW is a binding body of rules applied by and to states in their international intercourse. The rules rest partly on the assent of the states and partly on generally approved practise, assent to which is either presumed or, in respect of a particular state declining adherence, immaterial. International law is objective law after it has by time and experience acquired general recognition and application by international tribunals. The term international law seems to have first been used by Bentham, and it has almost entirely replaced the older term, law of nations.

The sources or agencies by which the rules of international law are formulated are either usage, giving rise to custom, or positive agreement or treaties. The difficulty with custom is one of proof. It is often determined only after submission of the issue to adjudication. It is always a troublesome matter to decide at what stage custom can be said to have become authoritative.

The evidences of custom are either documents tending to show what the practise of states has been or the writings of publicists to show general opinion or the decisions of international tribunals and national courts. The documents evidencing practise are treaties between particular states, municipal statutes and decrees, instructions issued by governments prescribing rules for diplomatic and consular officers, opinions of attorneys general and law officers on international subjects, diplomatic correspondence, the decisions of prize courts and other municipal courts, the history and record of international transactions, including the proceedings of international conferences. The writings of jurists have weight according to the authority of their authors; among the best evidences are the

resolutions of the Institute of International Law.

The principal treaties which establish international law are the great lawmaking treaties, which in so far as they are not merely a declaration of preexisting law are law only for such states as have ratified. Among important treaties are those embodying territorial settlements, so far as they concern the contracting parties, and treaties establishing administrative unions. Distinctions should be made between (1) treaties governing only two or a limited number of contracting parties, (2) general treaties binding a great majority of states and on matters of custom the others by implication and (3) a more or less universal rule of private law common to all or most civilized countries. The suggestion of an "American" international law as distinct from a universal international law, which attracted attention through the writings of Alvarez, is probably without substantial merit; admittedly certain problems are more important to the American continent than to Europe.

The sources of international law are thus more flexible and diverse than those of any municipal system. The method of its growth resembles that of the common law rather than the civil law, for it invokes as authority practise and precedent. The opinions of arbitral tribunals, now some thousands in number, are regarded as of primary authority; but any practise or opinion deemed to have weight may be legitimately used as persuasive evidence. The rules of evidence are not rigid. International law is therefore quite unhampered in its growth by restrictions of method or juristic technique.

Normally international law governs the relations of states. Not much time need be spent on the debate whether individuals are also subjects of international law. The word international would indicate that the rules govern nations. But individuals, pirates, recognized revolutionists, minorities, shippers of contraband, mandated territories, administrative unions, the League of Nations—all these are also the subjects of rights and duties declared by what is called international law. International law is a developing science. A movement is on foot to permit individual foreigners to sue a state under certain circumstances in an international forum, a privilege which would of course depend upon treaty. Is this relation between the individual and a foreign state still international law? Has the concept expanded so as to take in new topics? Was it too narrow in the first place? Are the "new subjects" merely the indirect objects of inter-

national law or are the new fields branches of public law affecting the relations of states with individuals? The answer depends on one's major premise and since it is definitional only is relatively unimportant.

International law constitutes but one aspect of international relations, in many respects not the most vital. The political competition for national aggrandizement, the acquisition or control of territory advanced or backward and of spheres of influence, the struggle for markets and raw materials, the quest for and grant of trade preferences, the height of tariffs and immigration policies, the size of national armies and navies—these factors, which to a large extent determine the economic and political relations of nations, have escaped up to the present time the control of international law. The scope of the subject is therefore limited to the legal and diplomatic relations between states in their treaty and what may somewhat inaccurately be called non-political aspects.

International law is thus concerned with the classification of states according to their degree of independence; their recognition and admission to the international community; the extent of national territory; the limitations upon national jurisdiction; rights upon the high seas and in international channels of communication and transit; the position of agents of the state, such as consuls and diplomatic officers; international ceremonial; extradition; the international responsibility of states to other states for injuries to aliens; the conflicting laws of citizenship; the conclusion, interpretation and termination of treaties; and means of redress for alleged injury, from pacific measures, such as diplomatic representation, mediation and arbitration, to the forcible prosecution of claims and interests leading up to war and including the vast complex of rules governing the relations of belligerents and neutrals in time of war. Within its limited field both in theory and in practise it is supreme, any municipal law to the contrary notwithstanding. Until many departments of state activity denoting political and commercial rivalry and reprisal are brought within its domain, the conduct of international relations cannot be said to be altogether controlled by law.

Aside from recent qualified experiments prohibiting war international law permits war, regarding it as something like a disease but expressing no moral judgment on the merits of the issue. The recognition of the legal rights of neutrals has indeed been regarded as one of the

crowning achievements of the nineteenth century. International law recognizes the legal validity of treaties imposed by physical force or duress, a type of contract which probably all civilized systems of private law regard at least as voidable. It recognizes the results of conquest. It permits imperialistic extensions of territory in backward areas and to insure temporary peace accepts inescapable facts. But so long as the gains derived by any nation from a successful assertion of physical force can secure legal sanction—and this up to the present time has been unavoidable—the system is necessarily somewhat immature.

Inasmuch as international law has been a growth responding to the need for regularized intercourse of states, it is natural to find that its roots go back to antiquity and that its development was influenced by the current learning of its many periods. Its origins lie in the intercourse of the Jews, the Greeks and the Romans with other peoples and it has early exemplification in the distinctions between friendly and enemy peoples, in the conclusion of treaties, in the conduct of war and the making of peace, in the exchange and protection of ambassadors and even in arbitration as developed among the Greek and later among the Italian city-states.

During the Middle Ages with a unitary church and emperor the rules for external intercourse were applied only among the Italian city-states, the Hanseatic towns and the feudal lords. The institution of chivalry came into vogue, but there was little need for interstate law. The Treaty of Verdun of 843 began the process of division in Europe; after the time of Frederick III (1440–93), the last of the emperors to be crowned by the pope, many Christian states arose. Then came the discovery of a New World, the scramble for possessions, the growth of sea trade, the respective claims to dominion over new land areas and over the sea, the break up of the empire, the Reformation, the system of independent states and the Thirty Years' War, which was ended by the Peace of Westphalia in 1648. Modern international law thus began with the rise of the European states system. Some regularized control of the competition arising from the intercourse of a group of so-called independent states became necessary, and the past was laid under contribution to furnish the materials for its ordered management.

Oppenheim lists seven factors before Grotius as preparing the ground for the growth of principles of international law: (1) the civilians, who

revived the study of Roman law and furnished to external relations the necessary analogies from private law, and the canonists, who furnished moral and ecclesiastical precepts; (2) the collections of maritime codes after the eighth century for the government of maritime commerce, which in turn nurtured the controversy over the freedom of the seas; (3) the leagues of trading towns for the protection of their trade and their citizens; (4) the custom of sending and receiving permanent legations; (5) the custom of standing armies, beginning in the fifteenth century, which hardened the rules of war; (6) the Renaissance, which revived interest in antiquity and in the philosophical and aesthetic ideals of the Greeks, and the Reformation, which promoted the spiritual influence of the Christian religion; (7) the numerous plans for universal peace.

The principal forerunners of Grotius, commonly called the father of international law because of his great work, *De jure belli ac pacis*, are Legnano, Vitoria, Soto, Suarez, Ayala, Bodin and Gentilis, all of whom made contributions of note. The importance of Grotius' work lies in the fact that it exerted so profound an influence not only on theory but on practice. Grotius' aim was to bring the practice of nations, especially in war, into conformity with what he called natural justice. He did not define the term. To the customary law developed by the practice of states he conceded obligatory force unless it contravened natural justice. In the peace settlements after many wars of the seventeenth and eighteenth centuries the opinions and doctrines advanced by Grotius and other jurists often found reflection.

Indeed publicists in the seventeenth and eighteenth centuries particularly exerted considerable influence on the development of the rules of law. Contemporary with Grotius was Zouche, who emphasized the customary or voluntary law of nations. The differences in approach gave rise to three different schools of writers: (1) the naturalists, who denied that there was any positive law of nations and declared that the latter is only a part of the law of nature, leading exponents of this school being Pufendorf, Thomasius, Rutherford, Barbeyrac; (2) the positivists, who rely on practice and deny any ethical or "natural" qualification, including in the main Rachel, Textor, Bynkershoek, Moser and G. F. von Martens; (3) the "Grotians," or "Eclectics," standing midway between the naturalists and the positivists, whose principal votaries were Wolff and Vattel. The idea of natural law as the

basis of a law of nations was fruitful in a period in which international rights and duties had to be deduced primarily from considerations of human reason and natural justice. The idea of natural law, however, also served as a sanction for the voluntary arrangements established by treaty. It thus prepared the way for the positivism which grew from the increasing reliance upon the treaty formulation of international rights that followed upon the many international wars.

International law after 1648 grew largely in the light of the rules adopted among the major powers in their negotiated treaties of peace or through prize courts and other institutions set up to determine international legal relations. The Peace of Westphalia produced the first great secular European conference and breaking down the theory of the unity of the civilized world opened the way to that conflict of nationalities and states which marks the present era. It inaugurated the conception of the European equilibrium through the balance of power, the guaranty of independence and the admission of Protestant states and republics on a par with Catholic states and monarchies. The wars of conquest of Louis XIV, which kept Europe in turmoil for half the seventeenth century, resulted in five important treaties: Pyrenees (1659), Aix-la-Chapelle (1668), Nijmegen (1678), Ryswick (1697) and Utrecht (1713). These with other treaties of peace established principles which find their place in the development of international law, such as the right of visit and search of neutral vessels by belligerents, the rule that free ships make free goods—not universally recognized until 1856—the necessity for blockades to be physically effective as a condition of their recognition by neutrals and a general extension of the freedom of the seas. In 1721 Russia entered the councils of Europe as a great power. The eighteenth century was marked by further wars and treaties of peace, which established political doctrines and not a little law. The peace of Aix-la-Chapelle (1748), Paris (1763) and Versailles (1783) emphasized the principles of the balance of power and rules governing the relations between belligerents and neutrals. The United States now entered the ranks as an independent state and was led by old colonial experiences to espouse vigorously the rights of neutrals, which through the First and Second Armed Neutralities of 1780 and 1800 had already obtained strong support from European powers.

The organization of the Holy Alliance and the

fear of its designs for the restoration to monarchy of the Spanish American republics led in 1823 to the Monroe Doctrine, a political principle of self-preservation, and to the doctrines of the recognition of de facto governments and non-intervention, which may be said to have become legal principles.

The Peace of Vienna aside from the moderation of its political terms made important legal contributions by extending the doctrine of the neutralization of strategic territories, by stipulating the freedom of navigation in international rivers, by establishing the modern scheme of diplomatic representation and by denouncing the slave trade. At the congress of Aix-la-Chapelle the law of nations was formally recognized as the basis of international relations and the maintenance of the status quo on the basis of legitimacy was posited.

The democratic upheavals of 1848 weakened the principle of legitimacy and gave rise to modern nationalism. Napoleon III developed it as a principle in France, from which it extended to Italy and to Germany; both of these nations were consolidated after wars. At the end of the Crimean War, when Turkey although still under the Capitulations was admitted to the family of nations, the epoch making Declaration of Paris (*q.v.*) of 1856 was promulgated. It abolished privateering and recognized generally that enemy goods on neutral vessels and neutral goods on enemy vessels are free from capture unless contraband and that blockades to be binding must be effective. Even powers that did not sign the Declaration, like the United States, recognized its validity in practise, and it is now generally regarded as universal law. The period that followed was marked by the growth of conventions for the amelioration of the cruelty of war. During the American Civil War in 1863 Lieber's celebrated *Instructions for the Government of Armies of the United States in the Field* (United States, Adjutant-General's Office, General Order, no. 100) was issued, and this has since become fundamental for land warfare. In 1864 came the Geneva convention for the amelioration of the condition of the wounded and in 1868 the St. Petersburg convention forbidding the employment in war of explosive shells beyond a certain weight. At Brussels in 1874 came the codification of the rules and usages of land warfare, which although unratified exerted much influence.

The period of political consolidation in Europe was followed after 1874 by the period of

dismemberment based on the so-called rights of nationalities, a movement which reached its apotheosis in the treaties of Versailles, St. Germain, Trianon and Neuilly. After the Russo-Turkish War of 1877 the Balkan states were set up and promptly became a source of conflict among the great powers. At the Berlin Congress of 1884 rules were laid down for the more regularized exploitation of Africa. The freedom of commerce, the neutralization of territory in the Congo district, the prohibition of the slave trade, the notification of occupations and the freedom of navigation of certain African rivers were stipulated. After the Sino-Japanese War (1894) and the gradual abolition of extraterritoriality in Japan the latter was admitted as a great power.

The third quarter of the nineteenth century was marked by the establishment of many international administrative unions, such as the International Telegraph Union (1875), Postal Union (1874), Protection of Industrial Property (1883), Copyright (1886) and innumerable others connected with navigation, health, transportation, commerce and labor.

The Hague conferences (*q.v.*) of 1899 and 1907 constitute a landmark in international law in that they codified or revised many of its branches. Their greatest contribution, however, was the adoption of rules of procedure for the arbitration of international disputes. The Permanent Court of Arbitration, before which some twenty cases had come by the end of 1930, was established at The Hague in 1899. The Declaration of London (*q.v.*) of 1909, ratified, however, by only a few powers, confirmed or adopted important rules relating to blockade, contraband, unneutral service, destruction of neutral prizes, transfer from enemy to neutral flag, enemy character, convoy, resistance to visit and search and compensation for breaches. An international prize court proposed at the Hague Conference, 1907, was never established because of inability to agree upon a method of selecting judges.

On the American continent the important Pan-American congresses of 1889, 1901, 1906, 1910, 1923 and 1928 and the Commission of Jurists at Rio de Janeiro of 1925 and 1927 for the codification of law considered or adopted lawmaking conventions on aliens, claims, arbitration, the recognition of new governments, boundaries, jurisdiction, corporations, immigration, diplomatic protection, extradition, freedom of transit, navigation and aviation, treaties, diplomatic agents, consuls, maritime neutrality, the

refusal to recognize the results of conquest and other subjects. A few of these conventions have been ratified by all the states and some by only a few, if any. But they marked a lawmaking trend and are not without importance as evidence of the growth of law. The Inter-American High Commission has fostered the adoption of numerous treaties facilitating trade and commerce. In 1907 a Central American Court of Justice was established, which lasted until 1918.

The twentieth century was moreover marked by four Hague conventions on private international law to facilitate legal recourse between country and country and by a large number of administrative conventions concerning the protection of health, wild life and agriculture and governing various aspects of transportation and communication. An increasing number of treaties embodying the obligation to arbitrate and conciliate disputes, with ever narrowing exceptions, also marked this period. Many of the rights of neutrals were violated by all belligerents during the World War, and a tendency on the part of some of the victors to dispute the validity of well established rules made itself felt.

The war exemplified a new weapon—false propaganda—which poisoned the minds of men and made wise negotiation difficult if not impossible. The Treaty of Versailles and its analogues of 1919 were the result. Through some of the practises sanctioned in that treaty, such as the confiscation of private property and the obligation of the defeated powers to compensate for all damage sustained by civilians regardless of source or wrongfulness, even including pensions, international law has suffered a setback, the extent of which cannot today be measured. But useful new principles were embodied in the treaties providing for the protection of minorities and in the mandates system. To offset the retrogressive tendency there has been a powerful movement in the form of the League of Nations theoretically aiming to make international relations more pacific and systematic and to minimize if not prevent future war.

It is an evidence of realism that in 1923 a conference at The Hague drafted a body of rules governing the use of radio and aircraft in time of war; but these have not been officially adopted as yet by any power. The post-war period has been marked by numerous efforts to consolidate peace, such as the Locarno treaties of 1925 and the Kellogg-Briand Pact of 1928. But they are all based on the preservation of the status quo regardless of its merits. The Kellogg-Briand Pact

is also encumbered by exceptions which render its utility doubtful. This peace movement has, however, made progress in the enlargement of the scope of obligatory arbitration of legal disputes at the behest of one of the interested parties only. The Permanent Court of International Justice established in 1920 has rendered over forty decisions, partly judgments and partly advisory opinions, to the Council of the League.

In 1930 an International Conference for the Codification of International Law was called at The Hague under the auspices of the League of Nations to resolve conflicts of nationality laws and to agree on the rules governing territorial waters and the international responsibility of states arising out of injuries to aliens. The conference drafted a convention dealing with some of the nationality problems but had to record its inability to agree on the other two subjects. Since 1919 there have been numerous financial and political conferences in Europe designed to bring some semblance of order into a disordered world. Many of these have arisen out of the Treaty of Versailles; perhaps the most important has been the series of conferences preparatory to the 1932 disarmament conference called to redeem the pledge of disarmament contained in article 8 of the Covenant. The success of most of these conferences has been limited.

In its juristic theory international law since the days of Grotius has struggled to reconcile its premises with the central realities of the European states system: the tremendous forces of democracy and nationalism. The constant changes in the internal and external organization of states emphasized the difficulties of the basic postulates which had obtained in international law since the Peace of Westphalia. These were contained in the doctrines of the independence and sovereignty of states.

The theory of sovereignty has impinged on international law in the assumptions that as law is the will of the state no rules of international relations have the force of law except by the consent of the state, and that as the state epitomizes moral values international law has only such validity as the state concedes. To explain the obvious fact that particular states have often been held bound without their consent and that the moral value of a rule has not been left to any individual state to determine the theory of auto-limitation was developed, by which the subjection of the state has been explained as voluntary. But a state which is bound only to the extent that it wishes to be bound is not bound at all, and the

experience of a century with international tribunals conclusively negatives any such conclusion. Law must be objective; and once it is recognized as a rule by international tribunals or majority practise, a state can neither refuse obedience nor be the judge of its moral value. A new state entering the community of states is bound immediately by all the rules of the organization. Its consent to any or all the rules is not asked. The assumption of the system is the equality of all states before the law; none can ask exemptions or favors.

If international law is entitled to be characterized as law—a question of definition—it must necessarily limit the omnipotence or sovereignty of the state. Austin was thus more consistent than Jellinek in denying the qualification of “law” to international law; for while both proclaim the ultimate sovereignty of the state as the source of law, Austin considers the law of nations as international morality only, whereas Jellinek explains its controlling character as resting solely on the will of the state, on autolimitation. Inasmuch as Austin demands of law that it be declared by a determinate sovereign, international law by definition could not be law to him but only moral precepts presumably not binding on the state when found inconvenient. The Austinians even assume that rules which rest on consent and agreement cannot be law, for only a sense of moral obligation makes them binding—merely another way of saying that they are not legally binding.

The fault is with the major premise. Only new international law derived from international legislation rests on express consent or agreement, and even then probably only for a comparatively restricted period would the unwilling state be able to deny the force of a rule generally accepted. But in the matter of customary international law, which embodies the bulk of the rules, neither complete consent nor agreement of states is necessary. Even Bodin, while an absolutist in the internal aspect of sovereignty, viewed external sovereignty as subject to the law of nations. Unfortunately many of his successors reversed the process; for they appear to regard sovereignty, viewed as a symbol of the state in international relations, as absolutely free from external restraint.

But no state can posit its freedom from the rules of international law. No state so professes. The mere fact that violations of international law occur and occasionally go unredressed is no evidence that the rules violated are not law, any

more than the no less frequent violation of municipal law is evidence of its non-legal character. International law is often uncertain; so is municipal law. The sanctions are somewhat different, but they are probably none the less effective and the interpreting agencies none the less active. International courts do not “enforce” international law; neither do municipal courts “enforce” municipal law. But the declaratory and binding decisions of international courts are observed and carried out with a uniformity equal to that prevailing in the case of municipal courts. The agencies for the enforcement of international law are not necessarily courts but other constitutional organs, usually the executive. The weakness of the system, which attracts a disproportionate amount of attention, consists in the inability to compel nations to submit their differences to a court and in the physical power of states, exercised on occasion without regard to law, to constitute themselves plaintiff, judge and sheriff in their own cause.

The World War and the resulting treaties punctured many illusions concerning the origin, causes, conduct, aims and accomplishments of the war. As a result there has arisen in some quarters a cynical contempt for international law. While naked force did override international law in many respects, mainly in the violation of neutral rights, the remarkable fact that in hundreds of instances international law was observed receives but little publicity.

The horrors of the World War have induced movements to abolish war, and attempts at its regulation have come to be regarded as an unfortunate admission of war's legality. Thus the jurists who take a functional view of international law, who hold that the provision of arbitral machinery should be the chief aim of international law, have looked with disfavor upon the post-war attempts of League agencies to secure its codification even where this codification means the introduction of not a little new law of a progressive character. But the exceptions to the Kellogg-Briand Pact constitute an almost universal admission of the legality of wars of “defense” and of the other wars excepted in the exchange of notes interpreting the obligations of the contracting parties. Thus there has also come a revival of the abstract distinctions made by Grotius and others between “just” and “unjust” wars, the privileges of normal belligerency to be extended to those who conduct the former but not the latter. How the two are to be distinguished and who is to be the judge are questions either

left open or to be decided by some League body. Those who would abolish war necessarily would abolish neutrality, which although once regarded as the most advanced stage of international law is frowned upon as unworthy, for war is deemed a crime to which no one can legitimately remain indifferent.

The League Covenant in articles 11 to 16 has sought to render war difficult by invoking the Council whenever war threatens and imposing the penalties of non-intercourse upon the nation which conducts war deemed by the Council to be aggressive. The definition of aggressor while apparently simple in the abstract is almost impossible of application, and unanimity of agreement in time of stress may well prove unachievable. It is probably fantastic to suppose that people having only a remote interest in the status quo can be made to endanger their existence in the pursuit of an abstraction, possibly undesirable. International law will have to go on with all its handicaps until the major nations realize that nationalism and the apparatus of nationalism are inconsistent with and destructive of an ordered world. Whether greater cooperation in regulating common interests, for which the machinery of the League is probably adaptable, can produce a deflation in tariffs, trade restrictions, attempted monopoly of markets and raw materials and other instruments of unfair competition and thus lead to a reduction of armaments and of war psychology and technique is still an unsolved question. That such deflation is essential to a more fruitful organization of the world and for the happiness of its people will hardly be denied. So long as each nation can determine the height of its tariff wall and the size of its armies, there is always danger of war. Reliance must be placed upon reciprocal agreements to curb the extreme manifestations of this liberty. The realization of the idea of a superstate—implying a surrender to an international body of control of tariffs, national policies, armaments—which would alter the position of nations to resemble the position of a state in the American union is probably remote. Until that time comes international law must be dealt with as it is; and yet attempts must be made to bring within its range those relations which now escape its control, to close many gaps, to deflate the causes of political competition and war and to persuade the nations to realize that cooperation even at the sacrifice of national self-sufficiency is a wiser and less costly exercise of independence than a recalcitrant insistence upon

one's own ambitions regardless of the common welfare.

Consult: The general treatises on international law have always been very numerous. Only the leading treatises of which there are recent editions will be given here. The American treatises are: Fenwick, C. G., *International Law* (New York 1924); Hershey, A. S., *The Essentials of International Public Law and Organization* (rev. ed. New York 1927); Hyde, C. C., *International Law, Chiefly as Interpreted and Applied by the United States*, 2 vols. (Boston 1922); Stowell, E. C., *International Law* (New York 1931); Wheaton, Henry, *Elements of International Law*, 2 vols. (6th ed. by A. B. Keith, London 1929); Wilson, G. C., *International Law* (8th ed. New York 1922). The English treatises are: Hall, W. E., *A Treatise on International Law* (8th ed. by A. P. Higgins, Oxford 1924); Lawrence, T. J., *The Principles of International Law*, ed. by P. H. Winfield (7th ed. London 1925); Oppenheim, L. F. L., *International Law*, 2 vols. (4th ed. London 1926-28). In French is available the great treatise of Fauchille, Paul, *Traité de droit international public*, 4 vols. (Paris 1921-26). The most useful German works are those of Liszt, Franz von, *Das Völkerrecht, systematisch dargestellt* (12th ed. Berlin 1925), and Strupp, Karl, *Grundzüge des positiven Völkerrechts* (4th ed. Bonn 1928). Italian: Anzilotti, D., *Corso di diritto internazionale* (3rd ed. Rome 1928), French and German translations (Paris and Berlin 1929). The treatises of Hershey, Oppenheim, Fauchille, and Anzilotti are especially rich in bibliography. An extensive survey of the international law treatises of the various periods is contained in Stier-Somlo, F., "Völkerrechts Literaturgeschichte" in *Wörterbuch des Völkerrechts und der Diplomatie*, ed. by Karl Strupp, 3 vols. (Berlin 1924-29) vol. iii, p. 212-27. The general treatises should be consulted for the more formal aspects of international law, such as its sources and scope, and for the relation of international to municipal law.

For the history of international law see: Viswanātha, S. V., *International Law in Ancient India* (Bombay 1925); Siu Tchoan-Pao, *Le droit des gens et la Chine antique*, vol. i- (Paris 1926-); Phillipson, Coleman, *The International Law and Custom of Ancient Greece and Rome*, 2 vols. (London 1911); König, E., "Zum Völker- und Kriegerrecht im Altertum" in *Zeitschrift für Völkerrecht*, vol. xi (1918-20) 155-89; Ward, R. P., *An Enquiry into the Foundation and History of the Law of Nations in Europe*, 2 vols. (Dublin 1795); Wheaton, H., *History of the Law of Nations in Europe and America* (New York 1845); Laurent, F., *Histoire*

du droit des gens et des relations internationales, 18 vols. (Brussels 1861-70); Walker, T. A., *History of the Law of Nations* (Cambridge, Eng. 1899); Redslob, R., *Histoire des grands principes du droit des gens* (Paris 1923); Nippold, O., *Le développement historique du droit international depuis le Congrès de Vienne* (Paris 1925); Koster, J., "Les fondements du droit des gens" in *Bibliotheca visseriana*, vol. iv (1925); Butler, Geoffrey, and MacCoby, Simon, *The Development of International Law* (London 1928). Such works as Phillipson, Coleman, *International Law and the Great War* (London 1915), Garner, J. W., *International Law and the World War*, 2 vols. (London 1920), or Mérignhac, A., and Lémonon, E., *Le droit des gens et la guerre de 1914-1918*, 2 vols. (Paris 1921) deal with the effects of the World War upon specific doctrines of international law.

Some works are devoted primarily to the theoretical development of international law as a science. Still of value are Kaltenborn, Carl von, *Die Vorläufer des Hugo Grotius* (Leipzig 1848), Bulmerincq, A. von, *Die Systematik des Völkerrechts von Hugo Grotius bis auf die Gegenwart* (Dorpat 1858), and Rivier, A., "Literarhistorische Übersicht der Systeme und Theorien des Völkerrechts seit Hugo Grotius" in *Handbuch des Völkerrechts*, ed. by F. von Holtzendorff, 4 vols. (Berlin 1885-89) vol. i, p. 393-523. The most prolific authority upon the theory of international law has been Ernest Nys, who has published *Le droit de la guerre et les précurseurs de Grotius* (Brussels 1882), *Les origines du droit international* (Brussels 1894), *Études de droit international et de droit politique*, 2 vols. (Brussels 1896-1901), *Les théories politiques et le droit international en France jusqu'au XVIII^e siècle* (2nd ed. Paris 1899), and *Le droit des gens et les anciens jurisconsultes espagnols* (Brussels 1914). More valuable for current use is Spiropoulos. The Italian writers are discussed in Pierantoni, A., *Storia degli studi del diritto internazionale in Italia* (2nd ed. Florence 1902). *Les fondateurs du droit international*, ed. by A. Pillet (Paris 1904) contains studies of the classic writers. The texts of the classics are being republished with translations and necessary critical apparatus in the *Classics of International Law* under the general editorship of James Brown Scott, vols. i-xii (Washington 1911-27).

In the history of the movement for the codification of international law the important names before the World War are Fiore, Bluntschli, David Dudley Field and Alvarez. The post-war codification movement is represented by many articles: Baker, P. J. N., in *British Year Book of International Law*, vol. v (1924) 38-65; Visscher, C. de, in *Académie de Droit International, Recueil des cours*, vol. vi (1925) 329-455; Hudson, M. O., in *American Journal of International Law*, vol. xx (1926) 655-69; Scott, J. B., in *American Journal of International Law*, vol. xxi (1927) 417-50; Niemeyer, T., in *Zeitschrift für internationales Recht*, vol. xxxvii (1927) 1-10; Urrutia, F. J., in *Revue générale du droit international public*, vol. xxxiv (1927) 619-26, and vol. xxxv (1928) 133-43; Strupp, K., in *Zeitschrift für öffentliches Recht*, vol. vii (1928) 152-210; McNair, A. D., in *Grotius Society, Transactions*, vol. xiii (1928) 129-41; Rauchberg, Heinrich, in *Zeitschrift für öffentliches Recht*, vol. x (1931) 481-526; Alvarez, A., in *Revue de droit international*, vol. viii (1931) 7-55.

For Pan-American particularism in international

law see: Alvarez, A., *Le droit international américain* (Paris 1910); Sá Vianna, Manoel, *De la non existence d'un droit international américain* (Rio de Janeiro 1912); Büchi, R., *Die Geschichte der pan-amerikanischen Bewegung, Völkerrechtliche Monographien*, vol. ii (Breslau 1914); Rauchhaupt, F. W. von, *Völkerrechtliche Eigentümlichkeiten Amerikas, insbesondere Hispano-Amerikas* (Berlin 1924); Moreno Quintana, L. M., *El sistema internacional americano*, 2 vols. (Buenos Aires 1925-26). A post-war phenomenon has been a similar development of a particularist claim for a Soviet international law: Korovin, E., *Mezhdunarodnoe pravo perekhodnogo vremeni* (2nd ed. Moscow 1925), tr. into German by I. Robinson-Kaunas as *Das Völkerrecht der Übergangszeit* (Berlin 1929); Mirkine-Guetzevitch, B., *La doctrine soviétique du droit international* (Paris 1926); Alexeiev, N. N., and Zaitzeff, L., "Sowjetstaat und Völkerrecht" in *Zeitschrift für Völkerrecht*, vol. xvi (1931) 72-99, 177-225.

For the basis of international law and its fundamental doctrines and problems consult: Higgins, A. INTERNATIONAL LEGISLATION. The term international legislation may be used in two senses: to describe the process by which changes are made in international law through lawmaking treaties or conventions and to refer to the results of that process which have been embodied in the content of international law. The term has not been in very common use in the past and is still somewhat novel. Indeed legislation as a means of developing international law has been much neglected until recent years. Few of the standard treatises deal with it. Many writers repeat that there is no international legislature, and some therefore deny that there is any international legislation. Yet it is now beginning to be appreciated that there is a process by which states can join together to change or add to the

law governing their relations and that the multipartite treaties and conventions concluded during the last hundred years constitute an important part of the prevailing law.

The Congress of Vienna of 1815 may be taken to have inaugurated the process of international legislation. Although that conference was not convoked for any such purpose, advantage was taken of the opportunity afforded by the assembling of representatives of a number of states to formulate certain provisions of international law. The formulation took the shape of instruments binding only on the states parties to them; but these states were so influential and the formulations so desirable that some of them have come to be accepted as applicable to relations between all states. A protocol of March 9, 1815, supplemented at the Congress of Aix-la-Chapelle in 1818, served as the formulated law on the classification of diplomatic agents for a whole century and it still has influence. The Final Act of the Congress of Vienna established the principle of free navigation on the international rivers of Europe by the merchantmen of all states, and until the adoption of a new statute at Barcelona in 1921 it served as the basis of international river law. Similarly the Conference of Paris in 1856 formulated a declaration concerning the abolition of privateering which has since been respected by belligerents not parties and which is firmly embedded in the existing law.

It was not until the middle of the nineteenth century, however, that conferences of state representatives began to be held to deal expressly with current international needs not filled by existing law. The revolution in international society wrought by improvements in methods of communication and transportation then called for international cooperation on a new scale. Problems had arisen for a solution of which traditional conceptions and practises offered no aid. Nothing short of continuous legislative activity would suffice. This was possible only through ad hoc international conferences, at which multipartite international conventions were adopted. Gradually these conferences became more frequent, more and more states sent representatives, forms tended toward some standardization and in time the importance of continuity came to be appreciated, with the result that various series of conferences were established. In some fields conferences continued to be convoked by single governments, which came to regard it as their prerogative to initiate action in those fields. For questions of maritime

law the initiative was that of the Belgian government; for other maritime questions, that of the British government; for questions of private international law, that of the Dutch government. In some fields the responsibility was shared by all the states interested; and where administration during the intervals between conferences necessitated the maintenance of permanent offices, public international unions, such as the Universal Postal Union, were created. These unions established a periodicity in the holding of conferences and made possible cooperative and systematic preparation for international legislation in advance of the conferences themselves.

Such developments led inevitably toward a more general form of permanent international organization. The unions were the precursors of the League of Nations, which was established in 1920 "to promote international cooperation and to achieve international peace and security." The activities of the League of Nations have resulted in a great quickening of the process of international legislation. The sharing of responsibility for conferences has tended to displace the calling of conferences by single governments. Most of the older unions have continued their work, which has been greatly stimulated and in some cases facilitated by the work of organs of the League of Nations. In addition many new fields have been explored, many new forms have been developed and the importance of continuity has been more generally appreciated. The result is that attention is now being given to many subjects which had previously been outside the range of legislative consideration. Conferences have become more frequent, preparation for them has become more thorough, their procedure has produced fewer possibilities of friction, their legislative output has been greatly increased and conventional forms have become standardized. The League of Nations has ushered in a new era of legislative effort. The volume of international legislation produced during the twelve years from 1920 to 1932 exceeded that produced during the entire century which preceded 1914.

It is still true that there is no international parliament with authority to legislate for the world of states. The nearest approach to it is the Assembly of the League of Nations, which seldom adopts acts and which does not purport to legislate except with respect to the organization of the League itself. The International Labor Conference also has some of the characteristics of a legislative assembly. If there is no interna-

tional legislature, it does not follow, however, that there is no international legislation. As long ago as 1907 John Bassett Moore could say that "of all the achievements of the past hundred years, the thing that is most remarkable, in the domain of international relations, has been the modification and improvement of international law by what may be called acts of international legislation." The history of the past quarter century has merely emphasized the truth of his statement.

Legislative progress has been particularly notable in certain fields. Legislation concerning telegraphic relations dates from the Paris Convention of 1865, which has been followed by numerous instruments; the St. Petersburg Convention of 1875 is still in force, but the regulations annexed to it were modified in 1925. The Universal Postal Union, organized under the Berne Convention of 1874, now comprises practically all the states of the world; periodic conferences have endeavored to keep the convention up to date, the latest having been held at Madrid in 1920, at Stockholm in 1924 and at London in 1929. For weights and measures the Paris Convention of 1875, modified in 1921, has served to create a common language for the whole world. Numerous conventions have dealt with the protection of industrial property, the latest general convention, which met in 1925, having been ratified by a large number of states; and with the protection of literary and artistic works, concerning which the Rome Convention of 1928 has recently been brought into force. The conventions drawn up by the peace conferences at The Hague in 1899 and 1907, the various conventions on private international law representing the work of six conferences held at The Hague and the conventions on maritime law resulting from the work of the unofficial Comité Maritime International as completed by the diplomatic conferences held at Brussels are all excellent examples of the fruits of the legislative process. The six international conferences of American states, held between 1889 and 1928, have produced many legislative instruments, not all of which have been brought into force.

Since the World War the greater volume of legislative instruments has come from League of Nations conferences. The legislation effected by the Communications and Transit Organization of the League of Nations is notable. In a few instances legislative instruments have been promulgated for signature and ratification by the Assembly of the League of Nations, e.g. the

Slavery Convention of 1926, the General Act for the Pacific Settlement of International Disputes of 1928 and the Convention for the Regulation of Whaling of 1931. More frequently, however, special conferences have been held; various conventions on the opium traffic, on traffic in women and children, on traffic in arms, on traffic in obscene publications, on road traffic, on buoyage and the lighting of coasts, on counterfeiting and on unification of laws of bills of exchange have been concluded in this way. In the field of labor legislation only two conventions had resulted from a whole generation of effort before 1914; since 1919 the International Labor conferences have adopted more than thirty labor conventions, which have been brought into force by various groups of states.

The technical problems which arise in international legislation are legion. Most of the work in international conferences is done by technical advisers sent by the various governments. The technical legal problems require close attention, although there is a tendency to follow more or less stock legal forms. The names given to instruments frequently carry little indication of their special character; an instrument may be called a treaty, a convention, a protocol, an act, a statute or by some other name. Signature is usually followed by ratification, and states which do not sign may be permitted to adhere or accede. Definitive acceptance of legislation has been greatly encouraged by the insistence of the Assembly of the League of Nations and by the work of the Secretariat of the League of Nations. The latter publishes periodical lists of signatures, ratifications, adhesions, denunciations and other acts relating to such acceptance. Problems of language, of reservation and of revision do not always receive uniform solution. Yet on the whole standards are developing which are being followed with remarkable regularity.

INTERNATIONAL ORGANIZATION. International organization is a phase of the relations among the nation states of the world. Individual nations exist in widely dissimilar physical situations and develop different social conditions and national interests, which result in divergent national policies both domestic and foreign. Foreign policies, programs of action in respect to other states, consist of desires or intentions of affirmative action, such as acquisition of territory; of negative action, as the denial of entrance to aliens; or of prevention of action by other nations, as the defense of territory. The satisfaction of national interests and policies requires in some cases only passive toleration from other nations; in other cases active cooperation. Where the latter is true, the development and execution of an international policy—a policy held by two or more nations—become desirable. For these purposes the nations need a system of institutions and procedures whereby national policies may be communicated by one nation to another, socially synthesized (internationalized) and executed. This body of institutions and procedures is referred to by the now fairly familiar phrase international organization.

National policy is internationalized at two stages: at the time of formation and at the time of execution; and in three ways: by international means of expression, by control (restraint and expansion) of such policy and by provision for its execution. International organization provides opportunities and facilities for the expression of programs of national policy and for the statement of national needs, interests and demands, which it endeavors to harmonize. These may be controlled while in process of formation if facilities are available at the time for subjecting the nations concerned to international influence; or their execution by individual nations

may be so controlled. The process of control operates essentially by providing opportunities for possible bargaining or exchanges of concessions among the nations. Such action and hence the process of control may be developed by the nations to such a point that the exchange becomes very indirect and the institutions and procedures employed for the purpose of effecting international control tend to obscure the essential character of that process. The results consist of increased or decreased benefit, including restrictions or expansions of liberty of action, in the case of individual nations, and in unification of policy among several nations, with consequent unity of action. Finally, the application of national policies after they have been harmonized and the expression, development and application of international policy as it has thus emerged become the main task of international organization, overshadowing the earlier action of harmonization.

International organization is thus broader than international government, which consists essentially of control exercised over one or more nations by one or more other nations. Such control may be exercised by an overpowering general preference shared by the controlled nation, for example, for the maintenance of treaty obligation, or by some form of pressure, such as military force. Thus the preference of the coerced nation in some current controversy is overpowered by considerations of value extrinsic to the issue at stake but important to the coerced nation. A certain amount of such coercion, control or government exists today among the nations without violating theories or principles which might seem to render it impossible. In this sense there exists an organized international control community, or international state, although there is no world state or world government. In its origin and even in its further development international government in this strict sense of the term is an outgrowth and expression of voluntary international cooperation, but its ultimate development is far different from its beginning. On the other hand, international organization as a whole remains more extensive than this type of internationalization and includes immediate and completely voluntary cooperation among the nations, just as socialization in the individual state proceeds not only by state control, coercion or government but also by strictly voluntary cooperation among individuals even in matters to which the state turns its attention, such as health and social work.

A complicating factor enters the problem at this first stage of its consideration. Since a nation is a group of individuals, any relation between one nation and another may involve a relation between the two nations as such, between one nation and one or more members or nationals of the other nation or between one or more nationals of one and one or more nationals of the other. The relations, procedures and institutions set up for the purpose of socializing or internationalizing national policies and activities may be cast in such form as to deal with the policies and activities either of the nations as such or of individual nationals of various states. When the latter method is adopted individual nationals are invested with relations, rights and obligations or allegiances to nationals of other states, to other states themselves and to the international community or state directly without the intermediation of their own national state. Under any logical theory of law there could never arise any real although there might be many apparent conflicts of allegiance in this connection; but the situation, inescapable in view of all the circumstances, is undoubtedly complicated both in fact and in principle.

Another difficulty arises here also. The national state developed under conditions in which international relations were few and international antipathies strong. There resulted doctrines of national independence or of sovereignty (*q.v.*) and of the equality of states (*q.v.*) which held that no state could logically, ethically or legally be required by another state or other states acting singly or in common to do anything it did not wish to do. Such doctrines apparently make unanimous consent necessary at every step in international cooperation—a formidable obstacle to effective progress. It seems difficult to reconcile national sovereignty and international authority in such a manner as to make possible international government by majority vote.

Such reconciliation is, however, made possible by the doctrine of the original agreement. The doctrine of national sovereignty does not deny to states the right to consent to any measure—they may even accept the obligation to do in the future something which at that time they may not wish to do. Hence by an original agreement the state may consent to the future operation upon itself by majority vote of international authority and even coercion. It might go so far as voluntarily to surrender its entire sovereignty without violating the doctrine of sovereignty. Numerous examples of this reconciliation occur constantly

in the conclusion and execution of treaty agreements, in the practise of international adjudication and in all forms of international government.

By implication international organization is to be contrasted strongly with simple international relations and with international politics. International relations consist of the geographical, mechanical, social and political relations among nations. International politics is the interplay of the policies of various nations before any process of international harmonization has been initiated. This interplay takes the form of relations of conflict and coincidence, identity, contradiction and competition. International intercourse in trade, travel and communication of various kinds bulks large in international relations and provides indeed the fundamental basis for most international organization; just as international politics with the waste and friction it engenders constitutes one of the principal reasons for the establishment of machinery and methods for synthesizing national policies.

True international organization differs even from what is at times called private international organization or internationalism, which in reality is neither international organization nor indeed international in any proper sense of the term but rather primarily what may most accurately be described as private world living or cosmopolitanism. In trade, travel and communication of various sorts individuals in different nations act without reference to their legal nationality or place of residence, across national boundary lines or not, as their interests dictate. This is true also of the hundreds of so-called private international organizations which spring up to express this unofficial world life. Private individuals and organized groups in different countries join together to form "international," or world, organs, such as the Institute of International Law and the Rotary International. These organizations hold meetings, maintain permanent offices, publish proceedings and literature of all kinds, stimulate world unity and international cooperation and at times lead the way to the establishment of official international organizations. But they are not in themselves entitled to be so regarded, and they pay relatively little attention to official nationalism or internationalism and often challenge the claim of these to respect and loyalty.

International organization is thus not the only possible form of world order. A world state based upon the type of cosmopolitan society which has just been described would provide

one alternative; if official internationalism is encouraged by world living it is also threatened with being superseded if it does not progress swiftly enough, and more radical progressives in this field clamor for the world state today. Imperialism is another form of organization which might conceivably lead to world unity. In times of chaos many men's minds turn in this direction, but the spread of democracy and nationalism tends to limit its field of activity.

The basic motives for the development of international organization seem to be three: the desire of human beings for satisfactions obtainable only from beyond national boundaries, which gives rise to the whole body of international intercourse; the desire of national states and their component citizens and officials for effective international cooperation in the regulation of this intercourse and in connection with all the activities of the individual state, many of which seem strictly national in character but demand such cooperation for their successful conduct; and a similar desire to avoid international friction and violence. Ideal aims of insuring peace and justice among nations are based upon these concrete desires.

Even in the presence of such motives, however, international organization could not develop in the absence of certain prerequisite and favorable conditions. Thus there must be more than one state in the world; in a single empire, which might constitute a world state and a means of securing world order, there would be no room for international organization. Moreover the existence of many states rather than of a few increases the need for organized interstate cooperation, broadens its basis and promotes its development in many ways. Substantial equality among the states is desirable and gross inequality fatal to this cooperation. Similarity of situation, need and policy, at least in order that points of common interest can be found by numbers of states, is requisite; individual states must have breadth of interest and policy in order to enter fruitfully into international cooperation. Stability on the part of the individual states is necessary; where states rise and fall too rapidly the maintenance of a system of international organization is impossible. Obviously too these states must be in contact with one another. Finally, there must exist a science of international organization if these facts and potential causes and consequences are to be adequately realized, interpreted and acted upon.

The functions to be performed by interna-

tional organization may be classified according to two standards: first, the form; and, second, the substance, or subject matter, of the action to be taken. The forms of action in international organization needed by the nations have already been suggested. The irreducible elements in international organizational activity seem to be formulation of law by agreement, administration of the law by international agencies and adjudication of disputes by international courts, which is perhaps a form of administration. The actions of individual states toward one another have no element of true international cooperation unless the states agree among themselves on common lines of action; they are then making law by agreement. The operations of international organization may be essentially analyzed into the making and execution of law; where the carrying out of the law is remitted to individual states, as it often is, there is international action only in so far as that action also is regulated by international law.

Here arises the problem of international coercion, or sanctions, the most critical and the most difficult problem in the entire field. Enforcement of international law is now left to the individual state possessing rights under that law, and international law defines certain modes of action available for that purpose: non-violent measures of litigation in national courts, diplomatic action, litigation in international courts, violent measures short of war (reprisals and intervention) and war. Obviously objectionable features of this situation lead to the suggestion of a system of international enforcement; all sound logic and theory of social organization and the entire history of government among men point irrefutably to this end. Although almost insuperable political and technological difficulties obstruct progress in this direction, this ultimate problem of international organization and international government must eventually be solved.

With regard to subject matter the proper scope of international jurisdiction and action may be stated to include in principle all matters of international interest. These comprehend the entire field of national life, of which no aspect is not of international concern, for many alien nationals and much alien property are present in every state. There are no "purely domestic questions" in international affairs today after the composition and organization of the individual state have been determined, and even here international interest and regulation are beginning to trench upon national discretion. Legally recognition of

this principle and of its exact implications in terms of concrete questions is left to interstate practise and agreement. The states may lag as far behind the factual situation as the sociological pressure for group action against individual liberty allows.

In practise one subject after another passes over from national to international regulation. All of the interests of individuals who are engaged in activity outside their own nations or on the high seas are involved: protection of life, liberty and property; health, morals, transit and communications; industry, trade and finance; and scientific and artistic needs relating to all of these. Many of the same interests of concern to nationals within their own states—especially communications, health, morals and scientific and cultural interests—are served by international cooperation. All matters upon which the individual state develops its own policies, legislates and takes administrative action come up for international treatment of those points at which they are of interest to other states.

Underlying all such subjects are the interests and the demands for peace and security on the part of the individual state as such. Preservation of peace and the protection of territorial integrity and political independence of the state against external aggression are the two most fundamental and important functions to be performed by international organization. The first is attempted both indirectly and directly. The indirect method is to treat by legislation and administration the fundamental causes of international friction. The direct method in case of acute controversy involves the use of diplomacy, including the "good offices" of third states where diplomatic connections are severed; the organization and use of the processes of inquiry, mediation and adjudication, including commissions of inquiry, in reality a species of administrative agent, and councils of conciliation, a form of international conference, and including also of course international courts and tribunals of all kinds; and the development of agreements not to resort to war but to employ the stipulated forms of pacific settlement. The second function of international organization is attempted by encouraging the conclusion of non-aggression and even mutual assistance agreements, but the provision of an effective general international guaranty of security depends upon solution of the problem of sanctions.

It is possible to distinguish six special forms and one general form of international organiza-

tion intended to serve the needs of the nations and the international community. Of the special forms, three: diplomacy, treaty negotiation and international law, may be described as pre-institutional in character; and three: conference, administration and adjudication, as institutional. International federation is the general and final form of international organization.

Diplomacy (*q.v.*), essentially an extremely primitive form of international action, is the communication from one state to another of an item of information or policy. Such action may be taken by any agency entitled to act for the state, as the chief of state or a diplomatic representative; but historically the resident diplomat has become most prominent in the process and the diplomatic corps has approximated the character of an international organ. Treaty negotiation, which grows out of diplomacy, consists of the making of agreements between states; it partakes of the nature of contract although it rises eventually to the level of statute legislation and constitution making (*see* TREATIES). International law (*q.v.*) is the most effective of the primitive devices for international control of national policy and action and for effectuating international policy and action. It consists of rules accepted by the nations as defining with binding authority their rights and obligations toward one another. It logically follows treaty negotiation and diplomacy in that it can hardly grow up without interstate communication, is much aided by treaty agreement and is broader and more stable than either. The customary law is amplified by international legislation (*q.v.*) and systematized by codification. It covers logically all phases of actual interstate relations peaceful or otherwise, including the later forms of international organization, although the descriptive science of international organization is not part of international law.

Conference, logically the primary form of institutionalized or organized international co-operation, consists essentially of diplomacy and treaty negotiation but gains its final character and status by the multiplication of the number of nations taking part. An international conference is a meeting of one or more delegates from each country participating. Participation is determined in the case of the single conference by the invitation of the country initiating the action; in the case of the conference in series, by prior international agreement. Attendance is wholly voluntary. The conference is opened by the chief delegate of the state in whose territory

the conference is held, unless other arrangements have been agreed upon; the conference elects its chairman and other officers, including a secretary, and creates such committees as it sees fit. The agenda of the conference is settled, usually in advance of the meeting, by agreement among the participants under the leadership of the convoking country or in accordance with procedure for that purpose stipulated in advance, as in the drawing up of the agenda by a permanent bureau. The agenda may be altered only with the consent of all participants, unless otherwise stipulated; actually items are rather freely added in the course of the conference and the tendency toward this practice is on the increase. The conference operates through plenary sessions and committee meetings; the real discussions and negotiations take place in the latter. There is little voting even in the plenary sessions, although provisions for majority decisions in matters of procedure are increasingly common today. In principle and for the most part in practice the conference rests upon and respects the principle of equality and especially the rule of unanimity. The conference is thus similar in character to the legislature or constituent assembly. It frames international constitutions, such as the Covenant of the League, and adopts statutes, such as conventions on maritime navigation. But in few cases as yet does the conference operate by debate and majority vote of delegates at discretion; rather for the most part it proceeds by unanimous consent of instructed delegates by way of the conclusion of treaty agreements. Even with these limitations the conference is the most dynamic and creative form of international organization.

Administration and execution in international government are ordinarily entrusted to bureaus or commissions of two or more persons and at times to individual officials. Such agencies, as, for example, the Universal Postal Convention, which define the composition and organization of the agency and the scope and mode of the action to be taken by it, are established by conventions among the interested states. Ordinarily it is the terms of a treaty, rarely general international law and still more rarely an international judicial award which is to be administered. Most international administrative agencies are provided in connection with some specific subject matter, such as river navigation (*see* INTERNATIONAL WATERWAYS); but the creation of a general international administrative service capable of functioning in connection with what-

ever questions arise has already appeared in such bodies as the Pan-American bureau and the League Secretariat. Such agencies consist in principle and to a large extent in practise of persons chosen not as representatives of the nations but as individuals expert in the subject matter to be treated. Professional technicians and administrators rather than political amateurs are needed. On the other hand, the administrative agency is supervised and controlled more or less closely by the constituent governments and the general conference or interim committee of the union of states maintaining the bureau. The action of the bureau impinges upon the participating states as such, upon their nationals and indeed upon other states and their nationals when subject to the jurisdiction of the former states. In this respect international administration approaches true international government more closely than does international conference. It is at this point moreover that the question of compelling national or individual compliance with international authority, the question of "sanctions," arises.

International courts serve to settle international controversies which arise in the course of unorganized international relations or in connection with international administration and which can be settled according to accepted law or treaty agreement. Arbitration is the settlement of such questions by general principles of law and equity, adjudication proper their settlement by positive law; but the difference between the two is not great. International controversies are sometimes submitted by the disputants to an international organ for investigation of the facts (commission of inquiry). Such a commission must be created by agreement defining its composition, procedure and powers; unless specially stipulated it has no power to pronounce upon the legal rights of the parties, but its findings of fact are conclusive. It is believed that authoritative establishment of the facts of a controversial case, together with the lapse of time necessary thereto, will aid peaceful agreement upon the merits. Going further, the parties may submit a dispute to a commission for recommendations as to settlement (mediation, conciliation); this practise is growing as a result of many treaty agreements. But the nations are not generally willing to submit their disputes for binding decision (arbitration, adjudication) unless these disputes can be settled by accepted law; this restricts the discretion of the judges and gives the participants an opportunity to foresee and argue

the fate of their contentions. Cases may be submitted only by agreement between the parties at the time or in advance of the dispute. International arbitration and adjudication are in reality essentially administrative action and also raise the question of enforcement. Actually international awards are with rare exceptions voluntarily obeyed; although this feature of the situation may change if obligatory submission develops very far. Finally, the future utilization of international adjudication seems clearly to turn not merely upon a desire for pacific settlement and a willingness to lose, if the loss be according to law, but upon development of the law itself and of forms of submission and procedure which shall render international adjudication more dependable and effective (*see* ARBITRATION, INTERNATIONAL; MEDIATION).

International federation follows as a general and synthetic form of international organization. It consists of the union of states for one common purpose or more and varies in membership and purpose from the alliance upward. The union is established by a formal agreement in which the scope and method of federal action are described and any federal agencies set up. Many details concerning the membership and duration of the union, its officers, organs and activities and the revision of its fundamental law must be settled in the original agreement. The treaty or convention establishing the union is in effect an international constitution. Strictly speaking, any union of two states constitutes an interstate federation, although the idea and the term are used chiefly to refer to multipartite unions. What is more significant is the fact that every union of states for the establishment of an international conference, court or commission is in principle a federation. In the creation of conferences and courts such federation is not commonly of long duration and is therefore not of great significance in this connection; on the other hand, administrative bureaus are frequently set up for indefinite periods and the unions of states supporting them provide the most numerous examples of international federation. The federal system seems complete when the union has a recurrent conference acting as constituent assembly or legislature, an interim committee acting as an executive council to supervise the work of the administrative bureau and perhaps even an arbitral board or tribunal to settle disputes in connection with the operations of the bureau. In such administrative unions the scope of action is generally narrow, but from the point

of view of structure and procedure international federation is present in all its essential qualities.

Both the foundations and the phenomena of international organization have varied considerably through the course of history. Certain forms of international organization originated in ancient times. The state system of the ancient world was not conducive to the development of such activity until the rise of the Greek city-state, but in Greece and even in the less favorable circumstances of Asiatic, African and Roman state systems a certain amount of international organization existed. Traces of international law, much diplomacy and treaty negotiation, some international conference and a large amount of international adjudication capped by serious experiments in international federation developed. All these were more or less ended, however, by the establishment of Roman imperial domination.

Certain of these activities—diplomacy, treaty making and international law—persisted into the early Middle Ages. Later arbitration revived somewhat, as did international conference and even a weak sort of interstate federation; for example, in the Hanseatic League. Until the sixteenth century, however, international organization was at low ebb.

The appearance of strong national states in place of the feudal chaos and weak empires of the Middle Ages and the revival of communication led to a reappearance of international organization. The half dozen great powers and their dependencies are surrounded by fifty or sixty more or less independent states; the volume of international trade, travel and intercourse of all sorts has grown tremendously. These developments inevitably stimulated international organization. International law arose and has continued to the present with an ever growing body of scientific literature and of official international treaty legislation and codification. Consular and diplomatic organization and practise have greatly increased; today there exist over twenty-five thousand consular and diplomatic agents. Thousands of treaties have been concluded, more and more frequently and on all sorts of subjects, with a notable increase in the number of multilateral conventions. International conferences in times of peace have become far more frequent, broader in scope and increasingly effective during the course of the past century; today the practise is very common, to some extent because of the use of special conferences instead of a single international assembly of general jurisdiction. Inter-

national administrative agencies, unknown prior to 1800, have multiplied gradually, especially since 1875, while more recent years have seen the creation of the general administrative services of the Pan American Union and the League. Finally, international arbitral tribunals, claims commissions and courts of justice have multiplied and broadened their activity, again since 1875, reaching their climax in the Permanent Court of Arbitration (*q.v.*) set up at The Hague in 1899 and the Permanent Court of International Justice (*q.v.*) established in 1921 under the auspices of the League of Nations. With more or less serious but constantly decreasing interruptions in times of war organized international cooperation has grown at an increasing pace during the past fifty years.

Various experiments in interstate federation were launched during the early modern period from 1500 to 1800 in the form both of alliances and of such national confederations as the Swiss Confederation and the United States of America; these were followed by projects for true international leagues put forward from time to time by Crucé, Kant and others. It was in the attempt to develop the Holy Alliance into a Concert of Europe, however, that contemporary international federation was foreshadowed. The concert led through varying success and failure to the setting up of the League of Nations and its related organizations, the International Labor Organization and the Permanent Court of International Justice. In the meantime the Pan American Union had been developing slowly into a weak rival federation in the western hemisphere.

The League of Nations has grown enormously in membership, structure and activity since its establishment in 1920. Provided with a deliberative if not legislative Assembly, an executive Council and an administrative Secretariat, although without coercive power, the League has also developed a number of auxiliary organizations (Health, Economics and Finance, Transit and Communications, Intellectual Cooperation), each rather pretentious in structure and function. Various commissions and special conferences function in connection with the League on such matters as disarmament, mandates and minority protection. The International Labor Organization is a duplicate league dealing solely with labor questions.

The historic development of international organization in terms of functions is reflected in the record of the development of the organs of

international cooperation. In earlier times conciliation of national policies in international law and diplomacy and treaty agreement was the chief objective, with some application of international law and treaties by arbitration. Not until the nineteenth century were elaboration of international policy in conference and its execution and international service to national needs by international administration established on an extensive scale. Even today the problem of international enforcement, or international sanctions, remains to be solved. In the meantime the other functions continue.

Any estimate of the effectiveness of contemporary international organization, including the League of Nations, turns mainly upon this question of the need for coercion in international organization. An amazing amount of international cooperation has proved obtainable on a purely voluntary basis, while constant discussion and comparison of national policies have led to much voluntary synthesis of them. On the other hand, the nations noticeably resent any verbal suggestion of coercion, although they act constantly under legal compulsion; in the efforts to establish a system of sanctions not the resistance of the potential victims but the reluctance of the prospective enforcers has held up progress. Furthermore cases may always arise in which voluntary compliance is not obtainable; in Manchuria and Nicaragua, for example, where weakness of state authority rather than action by a strong state constitutes the threat to peace and justice, this absence of international police power means that strong national states must be left free to act. In such cases the danger of illegal violence on the part of the intervening nations is always present. This great shortcoming of contemporary international organization and the unwillingness to see it remedied in the only way in which it can be remedied logically and practically lead to dangerous want of confidence and opposition to world order and evoke in one or two cases, such as the United States and Soviet Russia, policies dangerously close to absolute non-participation, non-cooperation, isolation or international anarchism. Such attempts to stay out or to get out of the organized international community prevent the fully effective functioning of that community. Certainly contemporary international organization is both valuable and effective in facilitating, stimulating and inducing voluntary international cooperation and in synthesizing national views and policies to that end; but it cannot be entirely adequate while it is de-

void of organization and procedure for international coercion in case of need. Such organization and such procedure would of course be of no value unless the members of the organization were willing to employ them; on the other hand, they will never be set up until the nations so desire.

INTERNATIONAL PAYMENTS, BALANCE OF. See BALANCE OF TRADE; INTERNATIONAL FINANCE.

INTERNATIONAL RELATIONS is a title that requires definition. It will be dealt with here as concerning, in the first place, the relationship itself, not the precepts and procedure regulating international relations, which constitute international law; nor the principles and procedures for conducting them, which correspond to diplomacy; nor the happenings consequent on that relationship, which is the course of history; nor even the products of the relationship either in new institutions, such as the League of Nations, the Soviet system and the British Empire, or in new ideas, such as pan-Europeanism, pacifism or pluralism.

In the second place, this article is concerned only with the relationship between nations. The social relationships between community units anterior or inferior to the sovereign nations of modern civilization are of interest here only in so far as they may suggest that these national states are but episodes in the present evolutionary epoch of civilized society. It is in this relationship between nations that the process of social evolution can be most clearly seen as one of periodic pendulum swings between centripetal and centrifugal tendencies. Thus the past two centuries exhibited an accelerating action of centrifugal decentralization, the "national movement," whereas the present century is experiencing an even more rapidly accelerating centripetal activity in the internationalism of capitalist and communist collectivities. These internationalisms although fighting on international and internecine fronts are none the less founding a new social synthesis in the international relationship.

The equations of international relations have true significance only as expressed in terms of the political factors and economic forces of a particular period. Thus at the beginning of the Christian era international relations in the orbit of the western social organism were regulated by the administrative and judicial institutions of

the Roman Empire; the "nations" were communities, each of which had a relation to the Roman rule but little or none to one another. It was in this imperial regulation of the rights of non-citizens that international law had its inception. Its emergence from the *jus gentium* and *jus fetiale* is as significant of the flux and reflux in the organization of civilization as the process by which the League of Nations has emerged from an international relationship reproducing in principle that which existed between the Greek city-states. The Roman Empire represents the most recent epoch in which the pendulum swing reached such an extreme point of centralized control over the external relations between communities that practically there was between them no international relationship at all. Since at the accelerated pace of present day change such an extreme point of centralization in a higher phase of the spiral of progress may at no distant date again be reached, it becomes important to reexamine the general course of international relations.

It is impossible to review here in any detail the process by which the pendulum swung back to decentralization: through the degeneracy of the Roman ruling class and its defeat by younger races; through the division regionally between the Western, or Latin, and the Eastern, or Greek, empires; through the dualism between regime and religion that led to the rivalry of empire and papacy; and through the decline of the diarchy exercised by chivalry and the church. But the political conditions under which the modern European nations were created should be noted because of the form they imposed on the modern European international relationship. This relationship can be very briefly and very broadly characterized as distinctively dynastic during the first phase of the sixteenth, seventeenth and eighteenth centuries and as democratic in the Anglo-Saxon definition of the word during the nineteenth and the first half of the twentieth century. For the modern nations emerged from a welter of warfare that during the fifteenth and sixteenth centuries swept away the internationalism of caste and creed by which chivalry and the church had diluted and prolonged Roman imperialism. The center round which the racial, regional and regimental rebellions of nationalism rallied, the new authority to which they appealed, the new rule on which they relied, were those of the crown. Having conferred on itself a divine right to a separatist sovereignty the crown then cut away above itself

the supremacy of emperor and pope; and having converted a social structure of status into a simplified internal relationship of sovereign and subject it then crushed out below itself the clerical, feudal, provincial, municipal and other organisms that claimed to share its sovereignty. Thus it was natural and indeed necessary that such international relationship as remained should be represented solely through the person of the national sovereign. It was also natural, indeed inevitable, that as the authority of the sovereign was based on armed force, so also the international relationship could be expressed through him only in terms of arms. Thus foreign policy and diplomacy in so far as they were not directly movements or menaces of war could be conducted only in a mentality of war. At best they based peace on a precarious balance of power; at worst they barred all progress by the wastage of warfare.

Even when revolts from the moral reaction and material ruin of the wars of religion or of the colonial and continental wars created the Protestant Reformation or the French Revolution and an effort to reconstruct the international relationship, results were nullified by the rivalries of the ruling dynasties and ruling classes and by their resistance to any redistribution of that responsibility for international relations that they had misused. Thus the "great design" of Henry IV and subsequent similar schemes for a world state, although they represented in form a real international idealism, in fact were little more than diplomatic gambits in the dynastic duels of the day. And one of the latest of these reconstructive revolts after an epoch of warfare, the Holy Alliance, soon convicted itself of being not so much an international peace council as a conspiracy against national progress.

In the first period of this dynastic phase of international relations the commonalty still retained some measure of control over the crown. As late as the sixteenth century monarchs depended on voluntary or voted supplies for the man power and money power for warfare. But this regime was more or less rapidly replaced by one based on professional forces and on a permanent fisc, the use of which parliament was in a position to veto only in certain countries and on certain occasions. By the eighteenth century the conduct of foreign affairs and the control of foreign policy had come to be universally accepted as a prerogative of the crown.

Consequently both the maritime competition for colonial supremacy that resulted from the

opening up of the Asiatic, American, Australasian and African continents to European exploitation and the military competition for continental supremacy in Europe that resulted from the collapse of the authority of church and empire were conducted by sovereigns unrestrained by any supernational regime or international regulation. The instruments of their struggle were professional soldiers, privateers and profit seeking subjects unrestricted by any realization of or responsibility for a common civilization. Somewhat later chartered companies holding concessions from the crown or corporations of international importance made a transition to the present principle of governmental responsibility. But just as there was little to choose between pioneers and pirates in the early colonial and commercial relationship so there was small room for choice on the continent of Europe itself, where the permanent representatives of the crown at foreign courts were expected by training and tradition to be as cunning as smugglers in tricking the law and as callous as slave traders in trading with the lives of their fellow countrymen and with the liberties of their fellow Christians. Family connections between the competing princes and common feelings between competing peoples were quite ineffective even to mitigate the evils of such a relationship.

Before the end of the nineteenth century the pendulum had started to swing rapidly back toward a new synthesis of society in respect to the international relationship. For a new civilization based on science was by then establishing itself swiftly throughout the European and American continents and as swiftly extending itself into the international relationship. One of the earliest and most evident economic expressions of this new scientific synthesis was the so-called industrial revolution, while its most prominent political beginnings were the British, American and French revolutions, which established the representative principle of government. And although the control and conduct of international relations remained for nearly a century thereafter a reserve of the ruling king or class, this became more and more a reserve remote from the real international relationship between peoples.

This reintegration of society proceeded from the bottom upward. It began by connecting up the international relations between individual nationals two centuries ago and has ever since been coordinating the international relations of national institutions. It has, for example, ef-

fectively organized international correspondence in telegraphic and postal unions under international regulation and rates. It has provided international security for the persons of individuals by contract and cooperation and for their property by a corpus of so-called private international law that is now better established than the public international law which concerns the relations between states. Thence it is passing from the individual to the institutional region of foreign relations by initiating a policing of civilized society. Inhumane exploitations of subject peoples for profit, such as the slave trade or the arms and drug traffic, and the extermination of valuable animals, as in the fur seal or osprey feather trades, have been regulated by international compact, while extradition has ended the exploitation of frontiers by crime.

By the end of the industrial revolution a century ago an international renaissance had been brought about by such agencies as travel, trade and translation, which had so broken down or bridged over the barriers of national frontiers and fashions that the individual citizens of western civilization were beginning normally to think of one another as akin in certain matters. Europe and America had come to eat, live and learn, to drudge and dream, to reason and be ruled, all on much the same lines and within much the same limits.

Unfortunately these emerging attitudes could be given no solid foundation either in Christian society or in scientific solidarity, as Christianity had gone too far from its original simplicity and sodality into ecclesiasticism and Erastianism, while science has not as yet left its laboratory attic for the arena of life. In economics the new international impetus has made even less progress than in ethics. Mechanism in production and mercantilism in commerce had set up competing and compacted national economic entities. Protection by tariffs, treaties and territorial imperialism became as favored a form of security as armies or alliances. Moreover this system with its support of private interests by public institutions made the interests both dependent on and dominant over the institutions. Thus commercialism like capitalism and clericalism became nationalized to the detriment of its own development and that of civilization. The wars of the nineteenth century were all more or less caused by commercial competition, while tariff walls and trade wars were and still are obstacles to the establishment of an international economic system.

Political union in any form can be effective only as the expression of an economic unification. For this reason the new internationalist ideals have as yet had little effect in the political realm against the national idols of sovereignty, security and self-complacency. A regulation of the reciprocal requirements of different regions in materials, markets and manufactures would by now have reorganized civilization and removed national rivalry but for conservative maintenance of national competition in the name of security. The competition for prestige and territory between the crowned rulers of the eighteenth century was less of a brake on progress than is the competition for production and trade between the ruling classes of the twentieth. In the eighteenth century there was as yet very little international relationship to represent; in the twentieth there is such a relationship both ethical and economic, but its political representation and realization are irreconcilable with the religion of private property and personal profit.

Accelerated reaction toward internationalism resulted from the World War—a reaction ethical in its realization of the evils of warfare and war fever and economic in respect of the material extremity to which the world was reduced by war wastage. The complete consequences of this incipient revolution in the international relationship cannot be dealt with here in detail. They represent a variety of different—and in some cases divergent—lines of advance and it would be hard to say which of these at present offers the best prospect of progress. Whether progress will come by a general reduction of armaments or by the construction of a supernational power and police in the political region or as a confederation of corporative states for reorganizing production and consumption in the economic region; whether it will be reached by the road of diplomatic negotiation or by that of democratic representation, are questions impossible to answer.

But one development must be dealt with, as it has for a century been inherent in the international relationship and seems likely to become imperative. That is the development in the field of capital and labor, the present tendency of property owners and proletariat alike to concentrate into two hostile camps irrespective of national feelings and frontiers. Labor, man power, as the greatest sufferer by the industrial revolution was the first to organize its wage slaves against the owners of wealth. But the money power now through its command of publicity, of

parliaments and of the other instruments of power has formed a fighting front which although less conspicuous has a far greater control of the international relationship. Moreover, whereas money power bases its activities on the national organism and is evolutionary, man power has an international objective and is revolutionary. The international ideologies of socialism and syndicalism, ethical in their propaganda and economic in their procedure, are so revolutionary in principle that they have as yet not succeeded in getting real power by peaceful means. On the other hand, money power exercised by the owners of wealth is so associated with the existing order and with national governmental authority that it has been unable hitherto to give effective expression to its real international interests.

But man power as such has now become effectively organized in communism. Thus there emerges a civilization in which man power and money power are no longer incorporated, as they were in the mediaeval guild, or merely competing for profit, as they were in the national craft union, or even in social conflict within the national state. Civilization is coming to be divided not only into economically conflicting class camps but also into ethically, economically and ethnically competitive continents: Asia and possibly Africa under the communist creed and constitution on the one side and on the other Europe and America under the capitalist creed and confederations. And very significantly both of these systems show a recent and remarkable expansion of the economic entity to the total or partial elimination of national sovereignty and separatism. The communist system was based originally on a concession of constitutional and cultural self-determination to constituent nations but severely subjected to central control of capital and commerce, production and consumption. This system is now well advanced into the second stage toward a new economic entity, that of building up underneath its complex political confederation a unified economic state structure. In the external international relationship the Soviet system is both economically and politically an organic whole and evidently it will eventually be so also in the internal relationships of its component nations. On the other hand, the capitalist system is still feebly feeling its way toward an internal control of private property and profit which will empower each national government to promote and participate in such international controls of capital, currency and commerce as

have become urgently necessary if the whole basis of private capitalism and national competition is not to break up. And although the League Council with its diplomatic and non-democratic constitution has been as yet little more successful than would have been its predecessor, the concert of Europe, and although such economic experiments as the Genoa or Hague conferences became less a cooperation of governments than a competition of big businesses, yet Europe and America are being speedily driven by economic pressure into economic solidarity.

The international relationship of the future seems therefore to be that of a fighting front between a progressive centrally controlled "corporate" state of communist Eurasia and a conservative confederation of more or less corporate commonwealths and countries. The relationship between the nations composing this capitalist confederation may in time become as peaceable as that at present established between the nations within the British Commonwealth or within the Bolshevik commonalty. But who can say whether war will then disappear or will only once again be concentrated into outbreaks—at longer intervals, of greater intensiveness and wider extension—in which civilization will itself be re-fused and reformed into a "Parliament of Man, a Federation of the World"?

INTERNATIONAL TRADE

INSTITUTIONAL FRAMEWORK. *History and Description.* International trade, or trade between the members of different political units, is the oldest form of commodity exchange. Primitive communities were so organized that trade was conceivable only between members of different tribes; and when the intracommunal exchange of goods developed, even where it did not grow out of intertribal trade it was patterned on the lines of the latter. A similar relation between international and domestic trade obtained at the beginning of the modern era; capitalistic wholesale trading was organized on an international scale before the domestic market expanded sufficiently to afford the requisite opportunity for men of large capital thoroughly imbued with the spirit of business.

It was only when domestic trade became as capitalistic as foreign commerce that writers were struck by the essential similarity of the two and the question was raised as to the fundamental criterion of difference. This was found at the time primarily in the fact that productive forces—labor, capital and entrepreneurial ability, not to speak of natural resources—do not move as readily across national frontiers as within the borders of a country. On the background of differences in the stage of economic development and in the structure of national economic systems, which are traceable in the last resort to differences in the course of history and in the national traditions deriving from it, the lower mobility of factors of production provides a more or less permanent basis for the exchange of commodities between different countries. The peculiarities of international trade, however, are not wholly explained there-

by; these are due to the existence of cultural and linguistic barriers, of differences in political structures and legal systems, of different commercial, monetary and financial policies.

For a long time the discussion of international trade was limited to the subject of commodity exchange and with good reason. The interchange of services and capital funds, the so-called invisible imports and exports, always formed a tiny stream alongside the mighty flow of goods; but it was relatively insignificant and could be disregarded. Since the end of the eighteenth century, however, it has come to acquire increasing importance despite the tremendous expansion of the volume of international commodity exchanges. At present there is no longer any justification for limiting the term international trade to the exchange of goods. It is now more nearly coextensive with the entire complex of international economic relations, with the movement across national boundaries of tangible goods, services, capital funds and even of population.

The end of the eighteenth century is generally associated with the beginning of the process of industrialization which originating in England has gradually transformed other countries. The importance of industrialization for international trade cannot be overestimated. Yet it must not be overlooked that the end of the eighteenth century marks also a turning point in the political history of the western world; at that time there were set in motion political forces whose action offers valuable clues to the understanding of the course of international trade. The establishment of an independent union of North American states and scarcely a generation later the emancipation of South American states signaled the downfall of the old colonial system. The unification of Italy and the creation of the German Empire signified an important victory for the principle of the national state and permitted the economic integration of large areas. The era of imperialism was inaugurated in the 1890's with the expansion of European nations to other continents through the acquisition of colonies and the annexation of distant territories. The organization of new states following the World War led of necessity to an expansion in the range of international trading, and the rising tide of nationalism in the east—in the Balkans, Egypt, India and China—brought in its wake a greater demand for foreign capital and signified a further extension of international economic relations.

The change in character and volume of international trade since the end of the eighteenth century was due to the interaction of a number of factors. First among them is the growth of population out of proportion to the increase in the domestic food supply. To provide sustenance for the surplus population industrialization became imperative; another means of relief was emigration to unexploited territories in the New World. Vast masses of people were thus set in motion first in England, then in Germany, later in Italy, the Balkans and Poland; Japan and China have also contributed their share. The stream of emigrants flowed into the United States, the countries of Latin America and to a smaller extent into other areas where the material conditions of existence were less favorable; thus virgin territories were settled and new civilizations created. Almost from the beginning the young countries exercised a demand for a variety of goods which could not be produced there, a demand which increased with the growth of population and the rise in its standard of living and acted as one of the principal stimuli for the further expansion of international trade.

Another important factor has been the development of industrialism impelled by technological invention. Since unit costs have been found to decline with an increase in scale of operations, the competitive pressure for lower cost led eventually to an expansion of manufacture beyond the capacity of the domestic market and a dependence upon foreign outlets for the surplus output. At first English textile manufacturers, later German ironmasters and in the course of time an increasing number of industries in various countries—chemical, electrical manufacturing, machine construction, automobile—found it essential to export a growing share of their output in order to maintain the scale of production. At present there is scarcely a major industry anywhere which is not dependent upon the world market for its sales. Specialization, one of the principal sources of the strength of modern industry, has encouraged this development: since the demand of any single country for a highly specialized product is rapidly met, the plant manufacturing it is capable of maintaining production at an undiminished pace long after the home market has reached the point of saturation. The reports of the experts presented to the International Economic Conference held in Geneva in 1927 show that the highly industrialized countries are the most dependent

upon the world market and that rationalization is likely further to accentuate this dependence.

Industrialization was preceded and accompanied by capital export, which became really important only in the second half of the nineteenth century. Individual capitalists and banks may have invested their capital abroad merely because they were attracted by high interest rates; but from a social point of view the significance of capital export lies in the establishment in the younger countries of new branches of production—the cultivation of cotton and tobacco, certain types of mining—or in the further development of already existing production, such as wheat growing. Foreign capital, which flowed into the countries on the American continent, into European colonies in Asia, Africa and Australia and which was of assistance in Germany, Russia and elsewhere in eastern Europe, accelerated the economic development of the debtor nations and enabled them to participate in the international exchange of raw materials and manufactured products.

International trade on a large scale was also connected with the development of transportation facilities. The construction of railways with a consequent large reduction in the cost of freight transport was an essential condition of long distance mass traffic and enabled the development of production in regions which had no direct access to navigable waters. Railroads brought the interior of Europe nearer the ocean and linked the American far west to international commercial routes. A few trunk lines also crossed other continents and brought them within the orbit of the world market. Railroads, which represent a total investment of about \$100,000,000,000 and which at least in the younger countries could not have been built without the aid of foreign capital, thus opened new opportunities for its investment also in agriculture, mining and manufacturing. The utilization of steam power in ocean shipping likewise facilitated international exchanges. Freight charges were so reduced that even bulky goods of low value—Australian wool, Indian jute, ore from Sweden and Spain—could be shipped to distant manufacturing centers.

The movement of population so important during the second half of the nineteenth century has in recent years diminished as a result of immigration restrictions in many countries. On the other hand, the international migration of capital has gained in importance and will probably loom even larger in the future. The early

tempestuous development of transportation facilities was succeeded by a period of moderate expansion; in this field Asia and Africa still offer vast opportunities. The principal effect of the interaction of these forces has been an enormous increase in demand for goods in all types of countries—old and young, "civilized" and "backward"—which in its turn has caused an expansion and intensification of international economic relations. At the same time there occurred a fundamental transformation in the character of international commodity exchanges as the economic systems of the various countries were reorganized and their consumption needs and production requirements radically modified. In this connection three types of international exchanges may be distinguished: between tropical and temperate countries, between agrarian and industrial countries and between industrial countries.

The exchange of tropical products for those of the temperate zone, the earliest variety of international trade, still retains some importance: coffee, rubber, cane sugar, tobacco, rice, spices and tropical fruits play a large role in international trade. The methods of production have of course changed fundamentally: the primitive agriculture of the natives has given way to the modern capitalistic plantation managed by Europeans or Americans. Yet the cultivation of tropical plants, the success of which is bound up with peculiar conditions of climate and soil, is in many cases almost as localized as it was a century ago, while an increasing number of countries have become dependent upon tropical products. Consequently tropical areas have been drawn more and more into the orbit of international exchanges; in fact the products of some tropical regions have entered the world market rather recently and only as a result of an increased demand for plantation wares.

The changes in the trade between agrarian and raw material countries on the one hand and industrial countries on the other are of greater significance. For the past hundred years food-stuffs have constituted an ever larger portion of the total volume of international trade. Industrial countries with a limited arable area, in which agriculture was developed far beyond the point of diminishing returns, have become dependent upon the importation of grain from abroad—from the United States, Canada and Argentina in the western hemisphere and from Russia and the Balkans in Europe. Similarly the domestic production of meat, animal fats and

dairy products in the industrial countries proved insufficient for the growing and prospering urban population; therefore cattle from South America and Australia and dairy products from Denmark and Holland became important items of import. International trade in industrial raw materials has grown even more; its rapid expansion was due to improvements in industrial technique which have led to the substitution of minerals of localized distribution, such as iron, copper, petroleum and potash, for organic substances and to the increased reliance upon certain organic raw materials, such as cotton, silk and jute, which can be grown only under climatic conditions of limited occurrence. Countries exporting foodstuffs and raw materials obtain industrial products in exchange; as a rule they are debtor countries exporting more than they import and using the surplus to pay interest and amortization charges on foreign capital invested in their railroads, public improvements, banks, plantations and the like.

Trade among industrial countries, the volume of which is much greater than is commonly believed, is the direct outgrowth of industrialism. European industrial nations do more trading among themselves than with agrarian countries. Germany, for example, sends three fourths of its industrial exports to European industrial countries, which provide a market also for three fifths of American industrial exports; similarly Great Britain sells a major portion of its exported merchandise in industrial countries. France trades silk and perfumes for machines and electrical appliances; England yarns, fine fabrics and agricultural machinery for coarser fabrics, chemicals and musical instruments; and the United States automobiles, agricultural and industrial machinery for silk and paper goods. Such interindustrial trading is traceable to specialization based on differences in natural resources, technical equipment and industrial tradition and is indicative of a marked degree of interdependence among industrial nations. It is to be observed that a large share of the output of highly industrial countries consists of producers' goods, such as machines, electrical appliances, chemical and metal products adapted to industrial and urban needs rather than to those of agrarian and raw material countries. The production of consumers' manufactures, among which textiles used to bulk very large in international trade, has now become more decentralized, each country relying more upon its domestic plants and less upon imports.

The type of commodities entering world trade determines the routes which it follows. Since the principal commercial countries of Europe and the industrial regions of North America as well as great sections of South America border on the Atlantic Ocean the transatlantic trade has been very important since the beginning of the modern era; at present its share of the total ocean freight movement is estimated at 70 percent. The transpacific trade is small in comparison, because the west coast of the Americas has not yet reached as high a state of industrial development as the east and the trade of the Asiatic Far East is still carried on mainly by way of the Indian Ocean. The importance of the Pacific as a trade route has risen, however, since the opening of the Panama Canal, which brought the Far East and the west coast of the Americas closer to the industrial areas on both sides of the Atlantic. Moreover transpacific traffic may be expected to grow with the more rapid economic development of the Far East. Similarly the Pan-American traffic is definitely on the increase, the oceanic trade between the two continents having profited greatly by the building of the Panama Canal. Euro-Asiatic trade, which is as old as European civilization, benefited by the opening of the Suez Canal and remains of some importance. The Indian Ocean is still the great trade route linking the British, Dutch and French East Indies to Europe; yet India's share of world trade was only 3.5 percent in 1900 and 5 percent in 1930.

In close connection with international commodity movements are the international movements of capital in the form of short term loan funds and long term investment funds. The flow of a considerable part of short term funds, that which represents immediate or deferred payments for commodity imports, parallels the movement of commodities but proceeds in the opposite direction. The movements of long term capital, an increasingly important aspect of international economic relations, are even more significantly if less directly related to international traffic in commodities. Capital exported from older and richer countries to younger countries and colonial areas opens new regions for capitalistic development and creates the conditions for the establishment of international commercial relations; indeed trade follows capital more than it does the flag. Whether as direct or as indirect investment such capital makes possible the capitalistic exploitation, more efficient and rational than the primitive destructive form,

of the natural resources of the younger countries and assures a continuous supply of indispensable raw materials and foodstuffs for the industries and population of the older countries. Foreign capital is also indispensable in the development of transportation facilities which link the distant areas of the younger countries to the central home markets and through them to world markets; the engineering trades of the capital exporting countries benefit directly from such railroad and ship construction. The establishment in younger countries of processing and fabrication plants—meat packing, milling, textile manufacturing—is often dependent upon foreign capital. Many of these industries furnish a desirable supplement to the production of creditor countries, while others tend to compete with the home industries of these countries; thus Indian cotton manufacture competes with that of Lancashire. The international movement of capital, whether to finance trade and industry or for purposes of speculation and government finance, sets in motion a return flow of interest payments. The capital importing countries are compelled to develop an export surplus of commodities, while the creditor countries unless they continue to export capital in excess of return payments of interest and amortization instalments must acquire a passive trade balance.

In addition to goods and capital funds nations also interchange services, of which the oldest is the commercial agency or brokerage service. Greeks, Armenians and Chinese, prominent in this field in the early history of international trade, still play an important part in certain quarters of the world; for the most part, however, modern foreign agents and brokers are English and German. Not infrequently the enterprises serving as intermediaries in international trade cluster about certain markets to which goods are shipped from all parts of the world and from which they are distributed to consumption centers. In England and in the Netherlands profits derived from the existence of such intermediary markets are fairly important in the international balance of payments.

Shipping is another such international service. The shipping companies of certain countries, better equipped, with good connections throughout the world and with the assurance of paying return cargoes, may undertake the transportation of freight for other countries. Before the World War English and German shipping lines were in this favorable position with re-

spect to most other countries, including the United States. Transit rail traffic in some European countries is sometimes similarly exploited to bolster the debit side of the balance of payments.

An international service next in importance to shipping is the short term financing of foreign purchases or sales. Such financing is often done directly or through subsidiaries by the banks of the older of the two trading countries. But it is not unusual for the banking institution of a third country, fortified by sound knowledge of conditions in the two trading countries and by ready access to international money markets, to undertake this type of business. Other services auxiliary to international trade, such as insurance of merchandise in transit, are as often as not in the hands of nationals of a third country which for historical reasons came to occupy an established position in this field.

Tendencies which have recently become manifest in the field of international services may foreshadow a future decline in the volume of international trade. The position of the intermediary country or market is being undermined by direct purchases in the producing country; Egyptian cotton, for example, is now purchased in Egypt instead of at auctions in England. The same result is achieved by international agreements which effect a direct exchange of the commodities of one country for those of the other—a variety of barter subject to the usual difficulties of determining a mutually satisfactory ratio of exchange. Direct purchase and international barter are exemplified to a degree in the Soviet monopoly of foreign trade which determines the quantity of imports and exports and tends to buy and sell in the primary markets. A similar decline in international trade services results from the development of national merchant marines and the establishment of branch plants on foreign territory.

Whatever the future of international trade may be, its volume has grown in the past despite the presence of numerous obstructing factors, as may be seen from the accompanying table. The number of participating countries has gradually increased until international exchanges have come directly or indirectly to comprise the entire world. The quantity and variety of goods entering world trade have experienced a parallel growth. Luxury articles no longer form a major portion of the volume; nor is it merely a question of selling abroad the surplus output. The principal driving force of international ex-

changes is found at present in the demand of advanced industrial countries for imported foodstuffs and raw materials; in other words, modern international trade affects the fundamental components of a nation's economic system. Thus in 1929 of the total volume of international trade 23 percent represented foodstuffs and 33 percent industrial raw materials as compared with 37 percent as the share of finished goods and 7 percent as that of services. Indeed the vitality of the most advanced and from a world point of view most important national economies is nowadays essentially dependent upon the continuation of normal economic intercourse with other nations.

WORLD VOLUME OF INTERNATIONAL TRADE AND THE SHARE OF PRINCIPAL COUNTRIES, 1840-1929

| YEAR | TOTAL IMPORTS AND EXPORTS (IN BILLIONS OF DOLLARS) | PERCENTAGE SHARE OF | | | |
|------|--|---------------------|---------------|---------|--------|
| | | UNITED KINGDOM | UNITED STATES | GERMANY | FRANCE |
| 1840 | 2.8 | 32 | 8 | | 10 |
| 1860 | 7.2 | 25 | 9 | | 11 |
| 1880 | 14.8 | 23 | 10 | 9 | 11 |
| 1900 | 20.1 | 21 | 11 | 12 | 8 |
| 1913 | 40.4 | 17 | 15 | 12 | 7 |
| 1929 | 66.7 | 14 | 14 | 10 | 6 |

The figures for 1929 are derived from United States, Bureau of Foreign and Domestic Commerce, *Commerce Yearbook 1931, (1931)* vol. II, p. 726-27.

Public and Private Regulation. Ever since it has come into prominence international trade has been considerably affected by the intervention of governments. At the beginning of the modern era mercantilist governments, resolved to augment national power by making the balance of trade as favorable as possible, gave most of their attention to the regulation of foreign trade and of domestic production connected with it; since that time foreign trade policy has remained an important element in the economic programs of governments. Direct regulation—through protective or liberal tariffs, commercial treaties and most-favored-nation agreements, reciprocity arrangements and import quotas—has always been a vital issue in public discussions. On these points various economic interest groups make themselves loudly heard and violent conflicts of interests arise, while

the interest of the national economy as a whole is not always carefully weighed in the balance. Protection of course is desired much more often than is free trade. Farmers and industrialists fearing foreign competition demand protection for their products and as a rule command sufficient influence with the government to obtain a fair degree of satisfaction. In agrarian countries, however, agricultural producers, who export most of their output and use a great many imported manufactures, insist on free trade. Similarly, merchants, especially in the seacoast cities, and shipping interests advocate free trade, as do those industrialists who are dependent upon export. Consumers also demand that commodities be offered for sale at low prices. Workers as consumers are largely in favor of free trade, but as producers they may be easily influenced by the fear of cheap foreign competition and led to demand industrial protection. Less attention is usually paid to regulation by administrative measures, a form of regulation which governments have developed in the course of time as a supplement to or even as a substitute for regulation by legislation and treaty. Like tariffs, administrative regulation may be free trade or protectionist in spirit and operates effectively and unobtrusively.

Among administrative measures those relating to currency are perhaps of most far reaching importance. Unstable currency means continual price fluctuations, which obstruct domestic and to a much larger extent foreign trade. The gold standard, adopted first in England and later in other countries, provided one of the essential prerequisites for the normal development of foreign trade. More recently central bank policy, which even under the gold standard is a most important instrumentality of currency regulation, has come to be guided to a certain extent by its anticipated influence upon the foreign trade of the country. A deflationist bank policy leads to internal stagnation; but a policy of inflation although it temporarily stimulates exports and discourages imports—a result which may be deliberately attempted, as in the case of England in 1931—injures in the long run both the country resorting to it and other countries maintaining close economic relations with it. Equally undesirable is the regulation of foreign exchanges sometimes attempted as a measure of administrative protectionism; for example, the foreign exchange restrictions employed in a number of European and South American countries in 1931 and 1932

amounted to a most drastic regulation of foreign trade designed to reduce imports to the absolute minimum.

The capital policy of the government is often related to its currency program; thus the maintenance of a stable currency standard is essential to protect the equity of the foreign capitalist in his investment. In addition specific protective measures are ordinarily taken by younger countries; the legal status of the foreigner and the negotiability of his securities are assured, and the interest on his investment is guaranteed even in private enterprises such as railroads. The general taxation policy as well as the promises given with regard to specific loans are also relevant. The governments of capital exporting countries are ordinarily less concerned with international capital movements. Yet even before the World War it was quite customary to discriminate in favor of colonies and certain countries of close political affiliations. Since the war measures of a restrictive character have come to the fore: complete embargoes on foreign loans have been imposed, investment bankers have been advised against loans to certain countries, and central banks have been forbidden to make loans on certain foreign securities.

In the field of transportation administrative regulation of foreign trade employs such devices as shipping and mail subsidies and numerous other forms of grants intended to encourage the development of regular freight shipping at low rates. Important seaports and canals as well as a great many railroad trunk lines have been built with government aid, and if necessary governments have assisted also in their operation. Not infrequently the public authority arranges railroad rates in such a way as to encourage the movement in and out of the country of certain important commodities, such as coal, grain, cotton and wool. Freight rate differentials are likewise used to impede imports and exports or to facilitate the movement toward certain seaports with a view to affecting specific world markets. Manipulation of rates is, however, a rather complicated procedure and often defeats its own purpose.

Under administrative action with regard to foreign trade must be included also: the work of the consular service, which protects, advises and aids national trade in foreign countries; the services of governmental agencies, particularly well developed in the United States and England, which supply information about export

possibilities and in general about business conditions in foreign countries; and the activities of national chambers of commerce in foreign countries, which often collaborate with government agencies in gathering and distributing information. Mention should also be made of the discontinuous but more or less periodically recurring activities, such as government assistance in the organization of international fairs and government action to promote international standardization of trademarks and merchandise nomenclature.

It will be observed that administrative regulation even where it is intended to encourage the development of foreign trade tends to give the trade and traders of one country preferred standing over those of other countries in foreign markets. Where administrative action aims at a reduction of imports it explicitly assumes a protectionist tinge. Such discrimination and protectionism, which have become rather common of late, escape to a large extent the regulative and mitigating influence of international agreements and go far toward nullifying even most-favored-nation arrangements. From a national point of view administrative regulation is therefore much more elastic and adaptable to current needs than regulation provided by legislation or treaty.

Government regulation interacts with regulation attempted by combinations of private interests for their own benefit. The cooperation of private interests, whether intended to facilitate penetration into foreign markets or to resist foreign competition, must of course operate within the framework of government regulation; but where it becomes really important private regulation may call forth a sympathetic or antagonistic modification of government policy. The government is more likely to be favorable if the benefits of such regulation are widely diffused; indeed where the combination of a large number of producers is essential, government assistance becomes well nigh indispensable.

The mildest form of private regulation is the allowance of export rebates on manufactured goods, when the prices of raw materials entering into production are raised by import duties or cartel agreements. Through such rebates prices of the manufactured goods are restored to their free trade level as far as export is concerned; the objections of exporters to protective duties and price fixing are eliminated thereby, and the sale of raw materials to export industries is left unimpaired. Export rebates may easily

lead to dumping, i.e. selling in foreign markets at prices below average production costs. Dumping has become important with the rise of industrial protectionism and the development of monopolistic combinations and has called forth protective measures in the form of antidumping duties. A substitute or a disguise for export rebates is sometimes found in the activities of national export cartels or export associations which aim at joint action on the part of national producers in foreign markets and the suppression of competition between them.

National export associations or cartels may develop into international agreements or cartels which are designed to eliminate competition in outside markets among their participants. Such international combinations attract attention out of proportion to their intrinsic economic importance because of the close connection with international politics. Before the war international cartels functioned in certain branches of the iron and steel industry and in the production of artificial dyes. After the war some of the old combinations were restored and many new ones organized, notably in copper, electrical equipment and international communications. In the field of shipping, agreements between American and German or American and British interests concerning the allocation of lines or freight and passenger rates have by now become traditional. An important prerequisite for the successful operation of international agreements is the existence of strong national cartels or the domination of the domestic industry by a few very large concerns; even so it has proved rather difficult to reconcile conflicting national interests and to maintain international cartels through periods of depression.

For certain commodities monopolistic combinations influencing international trade take the form of producers' pools which attempt to regulate supply: in the case of agricultural commodities pools are often aided by the government. A control of supply similar to the pool is sometimes undertaken by a very large privately owned concern which on account of its size and international connections has risen to a position of dominance. Attempts at control by such devices have been made repeatedly for wheat as well as for oil, rubber, bananas and matches. The success of such organizations hinges upon the command of enormous capital and ability to forestall the growth of competition from unexpected sources; as either of these conditions is very difficult to realize, attempts of

this sort have heretofore involved considerable risk of failure.

The experience of somewhat similar schemes of price regulation through valorization has proved equally hazardous. Valorization is a plan to maintain the world price at a predetermined level by regulating the flow of commodity to the world markets; it may involve the accumulation of large stocks which can be disposed of only very gradually. The best known instances of valorization—Brazilian coffee and Chilean nitrates—were carried on with direct economic and political support of the government. Nevertheless, the success of such schemes was found to depend upon favorable market conditions. Even after prices are stabilized there is present the danger of an expansion in production induced by the achievement of a profitable price; if this risk cannot be met successfully, valorization inevitably fails.

National Economic Systems and the World Economy. The importance of international trade for any one nation varies with the economic structure of the country and the magnitude of its productive resources relative to the population which must be maintained. Apart from an economically self-sufficient country, somewhat like Fichte's "closed state," it is possible to conceive several limiting cases in a country's relation to the outside world: the purely agrarian country producing only agricultural and mineral commodities and importing manufactures, the purely industrial country completely dependent upon the outside for foodstuffs and mineral raw materials, the trading and capital exporting nation whose entire stock of consumption goods is imported in payment for international services rendered by the country's merchants and for capital invested abroad. Of course no one country exemplifies perfectly any of these types, but countries do approximate one or the other of them. The importance for a country of economic relations with the outside world is reflected most clearly in its dependence upon imports: the larger the imports relative to the domestic supply and the more essential they are to sustain the smooth functioning of the economic machine, the greater the economic significance of international trade for the country.

The importance of merchandise movement in and out of the country is generally measured by the import-export per capita figure. On this basis it is found that foreign trade is more important for smaller nations and industrial countries than for larger and non-industrial countries.

Thus in 1929 the per capita foreign trade turnover in dollars was as follows:

| | |
|---------------|-----|
| Denmark | 266 |
| Netherlands | 243 |
| Switzerland | 228 |
| Great Britain | 219 |
| France | 103 |
| Germany | 100 |
| United States | 79 |
| Japan | 32 |
| British India | 6.5 |
| Russia | 5.7 |

The enormous preponderance of foreign trade in smaller countries is due to the importance of transit trade and to a greater dependence on foreign supplies because of small natural and man power resources. Industrial countries too are densely settled and contain a population maintaining a high standard of living. A better measure than per capita figures is the ratio of exports or imports to domestic production. Unfortunately total production figures are not available for many countries, and even for the most advanced countries they form a discontinuous and short series. It is estimated that Great Britain exports one fourth of its output and Germany one fifth; the industries and labor of both countries are thus in a very real sense dependent upon foreign markets. Other countries export a much smaller proportion, but with the expansion in their industries and the growth of their population a higher ratio of exports to output may be expected as a matter of course.

To industrial countries an expansion of the market through exportation, which means lower production costs because of a larger scale of operations and the possibility of greater specialization, offers the opportunity of a better utilization of industrial resources and of employment for surplus labor. In fact the Malthusian law of population is rendered ineffective for industrial countries through such enlargement and specialization of their industries, which assure the importation of foodstuffs from less developed areas. It is no accident that in recent years emigration from industrial countries has been smaller than from agrarian countries: the limits upon the productive capacity of the former are much more elastic than for the latter. Industrial countries also profit by the intensification of competition which accompanies expansion of the market. Technological and business inventions originating in one country are transmitted through these channels, and the domestic industries are forced to keep as efficient

as possible. National peculiarities are not necessarily eliminated thereby; on the contrary, they may often be turned to advantage in international competition. Attempts are made of course to eliminate troublesome competition, and the line between invigorating and destructive rivalry is not always properly drawn. Industrial countries are usually also creditor and trading nations. Their national incomes are increased by returns obtained from foreign investments, which are generally greater than would have been earned by investment at home, and by payments for services rendered in international trade.

The benefits derived from international trade by agrarian and raw material countries are the obverse of those enjoyed by industrial countries. The latter not only transmit to the former their industrial arts and their business methods but also supply man power and entrepreneurial ability. Similarly, foreign capital in the younger countries makes possible the exploitation of resources and the development of productive forces which would otherwise have lain dormant. The increased output finds a market in the older countries, which means also that the new countries become vitally dependent upon export, much concerned with the steadiness of the foreign outlets and extremely sensitive to international price changes; this applies with particular force to those countries whose exports consist virtually of one commodity. Nevertheless, the younger countries develop and grow into strong economic entities through their connection with the world market. The standard of living of their population is raised—modern dwellings, finer clothing and the like are demanded—and it becomes possible to accommodate a larger population. Some of the younger countries endowed with certain raw materials and a suitable population may imitate the older countries and attempt to become independent, at least in trades closely connected with agriculture and mining. The United States passed through this stage of economic emancipation in the first half of the nineteenth century and the examples of India, Egypt and the Balkans at present point to such a trend. Many readjustments become necessary in consequence; exports of such countries are reduced and they may be threatened even with a complete loss of their customary markets. The network of international economic relations, however, is not destroyed thereby; as countries become industrialized their inhabitants develop new needs, for the

satisfaction of some of which they must look to other countries.

The influence of international trade extends beyond the individual national economies. As the relations between them grow in scope and importance, there gradually develops an international economic system, with its own markets and auxiliary institutions, which in a certain sense functions apart from and in contrast to national economic units.

The world market is a congeries of supply and demand relations centering about certain commodities and entered into in varying degrees by all countries. As contrasted with national markets, which are influenced by policies of national governments, the world market is free from any restrictions of a non-economic character. World prices therefore reflect the underlying balance of economic forces much more accurately than do national prices. They register the influence of the entire supply of a commodity, including stocks and reserves, regardless of its spatial distribution. For this reason the world price may be lower than is desired by interests operating in national markets, as is attested by the history of grain, sugar, coffee, rubber and oil. It may even fall below the cost of production. In such a case no makeshift measures would help; the only remedy is a reduction of output which is slow and difficult because of the threatened loss of invested capital and which may be offset by the increase of output in another country. That does not imply that world prices may not be manipulated for short periods; more permanent artificial price fixing, however, as attempted through valorization schemes, by pools, international cartels and world wide combinations, fails in the long run.

Another important difference between world and national markets concerns the number and types of commodities which reach the world market. A great many commodities are not traded internationally because the cost of their transportation over long distances is too high as compared with their value, for example, building materials; or because they are adapted to specific demands of one region or country, as is true of most finished goods. The world market is naturally limited to those commodities for which either the demand or the supply is of an international character and which are produced in large quantities, mainly raw materials and food staples. Those which are capable of exact grading are dealt in through commodity exchanges; others, whose quality must be ascer-

tained by the buyer on the spot, are bought and sold at auctions. The location of such exchanges and auctions is determined by proximity to production areas and consumption centers; but once established they cannot easily be moved, because their effective functioning comes to depend upon a complicated network of wholesalers' and brokers' offices, financial institutions, transportation and communication connections and warehousing facilities.

World prices are in a sense not comparable with national prices. There is no world price level because there is no world currency whose purchasing power it would express. Moreover the world trade volume is but a part of national trade volumes; national price levels are affected by the prices of a number of goods which do not enter international exchanges—hence the permanent disparity between the purchasing power of money in the several countries. But for those commodities which are traded in world markets world prices exercise a decisive influence on national prices. Neither import nor export duties can establish a permanent differential between the two. Where the country produces an export surplus, the price of that surplus, which is determined in the world market, must eventually control the domestic price; where the country depends upon imports to satisfy its requirements, protective duties are economically justifiable only if they encourage the expansion of domestic manufacture to the point where it is capable of meeting in full the demand in the home markets.

As international economic relations grow in importance, influences transmitted through the world market come to play an increasingly decisive role in stimulating or depressing business in the various countries and produce a striking if imperfect parallel of prosperity and depression throughout the world. If the purchasing power of one country drops because of a special credit and agricultural crisis, the exports of other countries are more or less affected. Large bankruptcies and suspensions of payments are reflected in a drop of imports; and a stock exchange crash in one country may lead to default in obligations and a drop in security quotations in other countries. These observations apply most aptly to those countries which are organically integrated with the world economy; of course if prices, unemployment, security quotations or interest rates in a country fluctuate in a radically different fashion from corresponding economic indices elsewhere, it is

evident that a close relationship with the outside world has not yet been established. Even within the world economy proper, countries differ in economic structure and are not equally susceptible to international economic fluctuations; prosperity and depression are therefore not exactly simultaneous everywhere. Even in these countries changes in business conditions are still dependent upon purely domestic factors, such as crop conditions, efficient organization and management of the financial system, government policies, political upheavals and the like; and in each country, no matter how closely linked to the world economy, prosperity and depression bear a peculiarly national stamp and differ in many characteristic details.

International economic interdependence is reflected also in short and long term finance. Although the general level of rates in the several money markets is determined by causes peculiar to each market, nevertheless a fall of the rate below normal in one country will cause short term funds to flow out and induce a tendency to weakness in the rate in other money markets. Similarly, high discount rates in one market are inevitably transmitted to other markets and induce a corresponding stringency there. No central bank therefore can manipulate rates in its home market without taking into account the existence of other markets not equally subject to its influence. For long term capital international interdependence is not so pronounced. Still there are securities of high international standing which are traded on all the important exchanges and which pass from one country to another as easily as short term funds. Long term loans are sometimes floated with the participation of the financial institutions of a number of countries which take up the issue in agreed proportions; such loans are issued in terms of several currencies to suit the convenience of the buyers. Nor is mediation for long term investments unknown. Thus Swiss banks receive deposits from many countries and are in a position to finance the industries of various countries. In the post-war period London acted as an intermediary between French and American investors and German borrowers, and to a certain extent New York relented funds obtained from France and Great Britain to South American countries. The more customary type of relation in long term finance is, however, the direct one between the creditor and debtor nation and the interdependence is interregional rather than international in character.

International economic relations give rise to a number of international and interregional organizations of an auxiliary nature which facilitate the exchange of information, expedite communication and transportation and bring about the modification of divergent national practices to conform to international standards. Perhaps the most inclusive of such organizations is the Universal Postal Union. There is nothing corresponding to it in the field of transportation, but there exist a number of conventions between several countries regarding the use of railways. Similarly, there is as yet no international organization for bank clearings, although the Bank for International Settlements may eventually serve as such. The International Chamber of Commerce, the economic and financial section of the League of Nations, the International Labor Organization, the International Institute of Agriculture, the International Statistical Institute, provide facilities for the exchange of economic information among countries, carry out research on economic problems of an international character and serve to crystallize world opinion on economic problems. The work of these organizations becomes the basis of international agreements which when once entered upon limit the freedom of action of individual countries and create in the international field a counterpart to government action in national economic life. The list of international organizations of an official nature would be much extended were it to include also regional organizations such as those linking the United States and Latin America, the countries of South America among themselves, countries of central Europe and of the Balkans and the like. The number of semipublic organizations, congresses and agreements joining special interest groups in various countries is even greater. The post-war period was characterized by a striking growth in the number of such permanent or temporary international and regional organizations and by a remarkable extension in the scope of their activities. This development reflects the increase of economic interdependence among nations and an aspiration for the rationalization and systematization of international economic relations.

As the world economy is constituted at present no country, no matter how distant or how large, can be regarded as standing apart from it. Some countries need food for their population and raw materials for their industry, others need manufactured goods; and the development of many

countries depends upon a plentiful supply of foreign capital. No country is now economically independent; in the long run it needs trade with the rest of the world in order to survive, and in the short run it is influenced by the state of business conditions in other countries. There exists thus a broad economic basis for the solidarity of interests among nations.

Dependence upon the outside has its drawbacks as well: the profitable disposal of export commodities is uncertain because of potential foreign competition; the supply of essential imports may be reduced by artificial manipulation or by disturbances in the political balance; capital from abroad may be offered only at the price of concessions which restrict the freedom of political and economic action. These considerations may explain the drive for economic self-sufficiency which was apparent even before the World War and which was very considerably strengthened in the post-war period. The economic readjustments which took place during the war prepared some countries for a greater degree of economic independence than formerly they cared to enjoy, while the new states created by the peace treaties and Russia were eager to place their political independence on an economic basis. Thus old tariff walls were raised and new ones erected, and barriers heretofore unheard of were placed in the way of population movement across national frontiers. In the years 1919 to 1926 currency disorganization added its weight as an obstacle to interchange between countries, and with the beginning of the depression in 1929 restrictions were deliberately made more stringent as the result of a shortsighted policy of national self-preservation.

It does not seem to be open to doubt that the drive for national economic self-sufficiency is inspired by political considerations rather than by economic logic. There is at present no country, not excluding Russia, which commands all the economic factors in sufficient amounts to assure its independence; and even should such independence prove feasible it would not be advantageous from a strictly economic point of view. Technological progress and a rise in the standard of a growing population will in the future be accompanied necessarily by a further extension of international economic relations and an intensification of mutual interdependence. The forms which such relations will assume and the position of each country in the world economy will undoubtedly change. Some

of these changes, those due to industrialization of younger countries, can be more or less anticipated; other changes, those resulting from the progress of technology or from the shifting of the centers of control in various national economies, are at present only a fascinating subject for speculation.

FRANZ EULENBURG

THEORY. The theory of international trade consists in the application of general value and monetary theory to a special case in which the economic universe is divided into two or more partially independent units as the result of obstacles to the free movement of the factors of production or of the existence of distinct currency systems. To bring out sharply the consequence of immobility in the factors of production the classical writers assumed that there was absolutely no international mobility of the factors and that there was sufficient internal mobility to equalize the value productivity of each factor in all its employments. They entertained no illusions, however, as to the reality of these assumptions; they moderated their rigor upon occasion and conceded that the differences between inter- and intranational mobility of the factors were differences in degree rather than in kind. Hume explicitly stated that his theory of international equilibrium applied equally to trade between different regions of the same country. Cairnes treated international trade as a special case of trade between non-competing productive groups. Bastable suggested that the term interregional trade would be preferable to international trade because the differentiating factor between domestic trade theory and international trade theory was the existence of barriers to movement of the factors, of which distance was the most important.

The special significance of political boundaries in the study of trade should not, however, be overlooked. Political boundaries tend to correspond with physical barriers or to coincide with racial, linguistic, sentimental, legal, monetary and other differences in population and institutions which operate as hindrances to trade. Political frontiers moreover have been made the basis for the deliberate establishment of barriers to trade and to the free movement of the factors in the form of tariffs, administrative restrictions, immigration legislation, discriminatory legislation against foreign capital, business enterprise and the like. For political reasons the interest in foreign trade is greater than in internal trade,

and statistical information in all countries has been more systematically and fully compiled for the former than for the latter.

The theory of international trade has been generally treated in two main divisions: the theory of international values and the theory of the mechanism of international trade. In both divisions systematic exposition of positive doctrine has been largely confined to the English classical school and its modern English and American followers. Continental writers have either ignored the theory or have confined themselves to criticisms of the validity of its specific propositions but have not attempted to construct an alternative theory. An exception should be made for Pareto, who applied his general equilibrium theory to trade between regions as a special case. The old classical theory has been revised and expanded almost without exception by its own adherents rather than by its critics or as a result of their writings.

The classical theory evolved largely as an incidental by-product of current controversies on practical issues; in the selection of problems and the distribution of emphasis it still reflects clearly the special circumstances under which it was developed. It was never adequately integrated with the general theories of value and price and of money and banking, with a distinct loss to both bodies of doctrine. Moreover the theory has suffered from the fact that with Taussig as the outstanding exception its leading exponents have attempted comprehensive and systematic exposition only in the form of overcompact and over-abstract summaries, in which the short run complications, the details of mechanism and the necessary qualifications, to the elucidation of which they had often made important contributions elsewhere, were either wholly ignored or treated too summarily. Much of the criticism which has been directed against the classical theory of international trade is based on these inadequate summaries and would not have been undertaken by the critics if they had examined the lesser writings of its leading exponents.

The theory of international values has been expounded by Ricardo, J. S. Mill, Marshall, Bastable, Edgeworth, Taussig and others largely with reference to its bearing on the perennial tariff controversy. The central proposition of this theory is the doctrine of comparative costs. It was apparently first stated by Torrens in 1815 but was given special emphasis for the first time by Ricardo in 1817. Adam Smith saw only that free trade made available the benefits of what

Torrens later called territorial division of labor; it involved the specialization by each country in the production of those commodities which it could produce at lower real costs than could other countries. Ricardo argued that superiority in comparative rather than absolute real costs should and under free trade would determine what commodities a country produced. A country which could produce all commodities at lower (or at higher) real costs than other countries would nevertheless gain from trade if it specialized in those commodities for which its comparative cost advantage was greatest (or its cost disadvantage was least). Ricardo presented the doctrine in unqualified and highly abstract form. He supported it by an arithmetical illustration for two commodities and two countries in which it was assumed that prices are proportional to real costs, the latter consisting only of days of homogeneous labor and remaining constant with changes in output. He apparently believed that, given differences in comparative costs, each country under free trade would necessarily specialize completely in the production of that commodity in which it had a comparative advantage and that both countries would necessarily profit from the trade. He adopted an arbitrary but not inconsistent ratio of exchange between the export and the import commodities without apparently seeing any necessity for explaining how that ratio would in fact be determined. He failed, however, to bring out adequately the relation between his comparative cost doctrine and his general theory of international equilibrium.

A succession of later writers have attempted to fill in these gaps. Pennington and J. S. Mill showed that the reciprocal demands of two countries for each other's products in terms of their own products, operating within the limits of the comparative costs, determined the ratio of exchange between the two countries' products and that the equivalence in value of exports and imports (the so-called equation of international exchange) was a condition of equilibrium. The sufficiency of Mill's demonstration that there was a determinate ratio of exchange between export and import commodities has been questioned, and in later editions of his *Principles* Mill added some unsatisfactory analysis to take care of some cases in which he conceded that there were multiple points of possible equilibrium. These were cases, however, of foreign trade elasticities less than unity, which are unlikely to be of practical importance in the analysis of

foreign trade, when a country's entire exports and imports are involved and when for many commodities the purchases can readily be shifted from one country to another with a change in relative prices.

J. S. Mill showed that if one country was of much greater economic importance than the other, under constant costs the ratio of exchange of the two commodities might be the same under trade as they would have been in the larger country in the absence of trade, with the result that all the benefit from trade would go to the smaller country. Whewell showed that in such cases the larger country might not find it profitable completely to specialize in the production of the commodity in which it had a comparative advantage. Mangoldt and Edgeworth showed that if there were more than two commodities, reciprocal demand operating within the limits of comparative costs rather than comparative costs alone would determine which commodities each country would export and import; the result, however, would always be that each country would export commodities in the upper range of its scale of comparative advantage and import commodities in the lower range.

All the writers from Ricardo on and probably even in the mercantilist period were aware that the course of trade was determined proximately by comparative differences in prices; and those who presented their analysis in terms of costs expressed in days of labor—including J. S. Mill, who elsewhere rejected the labor cost theory of value—did so only on the assumption that prices and money costs were proportional to real costs and that days of labor were a satisfactory index of comparative real costs. The task of expanding or revising the theory to take account of differences of wages in different occupations and of other cost factors than labor is still far from accomplishment, but some of the writers in the classical tradition, especially Longfield, Cairnes and Taussig, have made important contributions.

If labor costs are the only costs and differences of wages in different occupations are proportional to differences in the attractiveness of the occupations, comparative real costs in terms of disutility of labor still determine comparative prices and therefore the course of trade. Where the differences in wages are due to the existence of non-competing groups, however, and are not identical in order or degree in different countries, specialization will fail to be carried as far as or will be carried farther than comparative real

costs justify; thus if in any country wages are higher in the industries with a comparative advantage in real costs and if the ratio of comparative wages exceeds the ratio of comparative advantage in real costs, that country will under free trade specialize in the production of commodities in which its real costs are comparatively high. In such cases, however, free trade by operating to lessen the volume of employment in the comparatively overpaid occupations would tend to break down the labor monopoly in such occupations, whereas protection of the high wage industry would tend to perpetuate it.

When factors other than labor are taken into account and variability in the proportions in which the different factors are combined in different industries in the same country or for the same industry for different outputs is conceded, it is permissible to adhere to the comparative real cost type of analysis only on the highly questionable assumption that money rates of remuneration are proportional to real costs even as between different factors, or on the less questionable assumption that in the absence of additional information forces operating to create disparities between real costs and money costs are as likely to be in one direction as in another and will therefore tend to offset each other. On this last assumption comparative cost analysis establishes only a presumption rather than a demonstration of the economic desirability of free trade.

The older writers adhered to the assumption of constant costs, under which average and marginal costs are identical. Later writers pointed out that if production is subject to increasing costs, specialization will tend to take place in accordance with comparative marginal rather than average costs. If the cost curves have different degrees or directions of inclination as between different industries in the same country or as between the same industries in different countries, then the scale and possibly even the order of comparative marginal costs of different commodities in two or more countries will not be fixed but will vary with different degrees of specialization.

Several writers have argued that if a country finds itself at a comparative advantage in industries subject to increasing costs and at a comparative disadvantage in industries subject to decreasing costs, it may lose if it specializes in accordance with comparative costs. If decreasing costs are due to net internal economies of large scale production, individual marginal cost and industry marginal cost will tend to be identical;

and even under free trade no resources will be transferred from decreasing to increasing cost industries when they would have greater value productivity in the former. If decreasing costs are due to external economies, there is possibility of loss to a country from specialization in accordance with individual marginal comparative costs, since the increase in cost due to the contraction of the decreasing cost industry will be borne chiefly by others than those responsible for the transfer of productive resources from it to other industries. But if the external economies are a function of the size of the world industry rather than of the national industry, as may well be the case, transfer abroad of a portion of the national industry will not reduce these economies; and specialization in the increasing cost industries will not be carried farther under free trade than is justified by the comparative value productivities of the transferred resources in the two types of industry.

The most commonly used test of the existence of national benefit from trade, originating in the early part of the eighteenth century, was whether or not a unit of import commodities could be got indirectly through trade at a lower real cost than that at which it could be produced at home. This is still the best available measure of benefit from the marginal units of trade, when expressed in terms of the relative costs of direct and indirect acquisition of the marginal unit of a particular commodity. It is unsatisfactory, however, when used to measure the amount of benefit of trade as a whole, since, as Malthus pointed out, when the imported commodities can be produced at home only with great difficulty, the excess of the cost of producing them at home over the cost of obtaining them in exchange for domestic commodities may far exceed the total national income and may approach infinity. Under free trade a country employs a bundle of productive factors different in size and constituents as compared to restricted trade to obtain a bundle of consumable goods also different in size and constituents. J. S. Mill on one occasion claimed for trade that it increases the national supply of all commodities. Where this is the case it is an unambiguous demonstration of the existence of benefit from trade, if one disregard considerations relating to the distribution of national income or to the comparative intrinsic desirability of the different possible modes of employment of the country's productive resources. This result is not inevitable, however, for under free trade the consumers in the aggregate may choose to con-

sume less of some commodities and more of others than under protection. Adhering to the abstractions listed above the national case for trade is still unambiguous, if on the basis both of their relative market values in the absence of trade and of their relative market values under trade the increase in those commodities which become available under trade in increased volume exceeds in value the decrease in those commodities which become available under trade in decreased volume. From the cosmopolitan point of view trade will meet these tests more often than from the national point of view; and, except for the special cases of national external economies or of trade by nationally monopolized industries without foreign competition, long run restrictions on trade will never meet these tests whether from the cosmopolitan or from the national point of view. The classical theory of international trade does not, as many of its exponents have supposed, demonstrate the national profitability of trade under all long run circumstances, but it does establish strong presumptions in its favor under most practically realizable circumstances and leaves the situation ambiguous in most of the other conceivable circumstances.

So far the discussion of the benefits from trade has taken into consideration only costs, quantities of commodities and relative market values. For a complete analysis it would be necessary also to take into account the variable desires for or utilities of commodities, including consumers' surpluses. But all attempts so far made to introduce utility analysis into the theory of international trade have rested on the inadmissible identification of national demand schedules with national utility schedules.

Other concepts have been used to gauge the trend of benefit from trade as distinguished from its absolute measurement. The oldest, going back to the mercantilist period, is the amount of import goods obtained in exchange for a unit of export goods. This might be called the "commodity terms of trade." Given a common base year and base value for both indices, the trend of the ratio of the export price index to the import price index would measure the trend of the commodity terms of trade, with an increase in the export price index relative to the import price index signifying more favorable commodity terms of trade. A more significant although less used concept might be designated as the "factoral terms of trade" and would indicate the number of units of other countries' products which could be obtained in exchange for the

output of one unit of a given country's factors of production. This concept takes into account both the commodity terms of trade and the costs of production of the exported commodities. For some purposes this concept could be modified so as to take into consideration also the factoral costs of production of the other country. Taussig has introduced a third concept, which he calls the "gross barter terms of trade" to distinguish it from the commodity terms, which he calls the "net barter terms of trade." By the gross barter terms of trade he means the ratio of the physical volume of imports to the physical volume of exports or of their respective money values after correction for changes in the value of the monetary unit. On the ground that imports are what a country gets as a result of its foreign trade and exports what it gives he maintains that the higher the value of imports as compared with exports the more favorable the gross barter terms of trade. This concept is superior to the concept of commodity terms in that it takes into account volume of transactions as well as unit exchange ratios, but it suffers from the defect that it treats credit transactions involving liquidation of previous indebtedness or the incurring of new indebtedness as if, for the time being at least, they were equivalent to the grant or the receipt of free gifts.

Torrens and Longfield appear to have originated analysis of the changes in the terms of trade caused by specific types of disturbances in a preexisting equilibrium. In connection with the controversy as to the relative merits of unilateral and reciprocal free trade during the 1830's Torrens maintained that the unilateral abolition of a tariff would result in an unfavorable shift in a country's commodity terms of trade. Senior and other economists, obviously influenced by their hesitation to make any concessions to the protectionist doctrine, disputed this but it was conceded by J. S. Mill and later writers. Longfield (*Three Lectures on Commerce and One on Absenteeism*, Dublin 1835) replied to the denial by Senior and McCulloch that the Irish suffered economic loss from the absenteeism of their landlords by pointing out the unfavorable effect on the Irish commodity terms of trade which such absenteeism would tend to have.

In the nineteenth century it was generally agreed that the export of capital or the remittance of subsidies or tribute abroad tends to make the commodity terms of trade move against the remitting country while the process of transfer is under way. The post-war discussion of the

transfer phase of reparations and interallied debts has resulted in a fuller analysis of the problem and in serious questioning of the old conclusions. In the traditional mode of dealing with the question it was argued that the preliminary export of gold by the remitting country would lower prices in that country and raise them in the receiving country and that such a relative movement of prices was necessary if the remitting country's exports were to increase and its imports to decrease sufficiently to transfer the payment in the form of goods rather than money. But this can be granted without conceding that the export prices of the paying country need necessarily fall relative to its import prices. The transfer of spendable funds from the paying to the receiving country will lead: (a) to an increased monetary demand in the receiving country for both its export and its import goods; (b) to a decreased monetary demand in the paying country for both its export and its import goods; (c) to an increased monetary supply in the paying country of its export class of commodities; and (d) to a decreased monetary supply in the receiving country of its export class of commodities. Of these changes only (c) and (d) are in character such as to establish a presumption in support of the traditional doctrine. But the net effect of all these changes on the commodity terms of trade will depend on the elasticities and the relationships to the domestic commodity supply and demand functions of all of these elements, and a definite solution would require quantitative analysis in terms of all the significant demand and supply functions. The a priori presumption will be stronger, however, in support of the proposition that the factoral terms of trade will shift against the paying country and in favor of the receiving country. There will be even a stronger presumption that the gross barter terms of trade will shift against the remitting country; i.e. that the physical volume of its exports will increase relative to the physical volume of its imports. In order that this should not occur it would be necessary for the commodity terms of trade to shift sufficiently in favor of the remitting country to make possible a relative increase in the aggregate value of its exports as compared to that of its imports, while no change in the aggregate physical volume of its exports as compared to that of its imports takes place.

The theory of international values usually works with comparative real costs and with reciprocal supply and demand functions of one commodity or class of commodities offered or

demand in terms of another commodity or class of commodities received or given in exchange. It abstracts from money, monetary prices and monetary supply and demand schedules. Bastable heralded as Ricardo's greatest contribution to the theory the argument that international trade in a money economy produces the same results as would take place under barter. This abstraction from money was useful as a means of avoiding the complications of a changing value of the standard of measurement itself and of emphasizing the more fundamental factors underlying the monetary phenomena. It has been criticized, however, as leading to the mistaken impression that the monetary mechanism was purely passive and was not itself a factor contributing to the determination of the nature of and the benefit from trade.

In developing the theory of the mechanism of adjustment of international balances the classical economists did, however, take explicit account of money, money prices and the monetary mechanism; and in fact they often expounded it as an integral part of their monetary theory. The classical theory of the mechanism of adjustment of international balances was first clearly formulated in its main outlines by David Hume and was closely approached even by earlier writers; it was used as a refutation of the mercantilist contention that foreign trade can and should be so regulated as permanently to augment the national stock of money. The theory insists upon the existence of a self-regulating mechanism for the international distribution of metallic money, whereby each country gets the amount of money necessary to maintain equilibrium in its international balances. It maintains that if the quantity of money in a country is increased, then, other things remaining the same, prices in the country will rise, exports will consequently decline and imports increase, with the result that the foreign exchanges will move against the country and will tend in some degree to bring about a restoration of equilibrium in the trade balance. If, however, imports continue to exceed exports in value, the exchanges will move to the gold export points; gold will be exported to liquidate the adverse balance of payments; prices will consequently fall at home and rise abroad; imports will fall and exports rise; and equilibrium will be reestablished with the foreign exchanges at or near par, no further gold movements, an even balance of trade and prices higher than before both at home and abroad. This is essentially Hume's account and was reproduced

without substantial change by the classical economists in their general treatises.

For some phases of the mechanism, however, the classical economists introduced in their lesser writings a number of important elaborations and qualifications and in controversy among themselves developed divergent and rival explanations. The first important advance was made during the bullionist controversy in England in the first quarter of the nineteenth century. The results of an expansion of convertible paper currency, circulating alongside and on a parity with standard metallic money and issued freely by a number of banks subject only to the requirement of convertibility, were analyzed by Henry Thornton, Ricardo and other writers. Special attention was paid to the question of the dependence of the amount of note issue by country banks and therefore of the general price level on the amount of note issue by the Bank of England, Ricardo maintaining and others denying the necessity for any such close dependence. Thornton initiated analysis of the mechanism of restoration of international equilibrium when disturbed by other causes than variations in the quantity of money, such as harvest failures or payment of subsidies. He maintained that in such cases equilibrium was restored by the same mechanism as that invoked by Hume to explain the restoration of equilibrium when disturbed by changes in the quantity of money. Wheatley and Ricardo denied this and contended that in the case of non-currency disturbances equilibrium was immediately restored through the automatic adjustment of the demands of the different countries for one another's products, without setting into motion any intermediate mechanism of exchange rate variations, gold flows and price level changes. A number of writers participating in the bullionist controversy made it clear that they saw the distinction between the commodity balance of trade and the balance of immediate indebtedness and that they realized that for the theory of the mechanism of international trade the commodity balance of trade had significance only as the predominant element in the larger balance of immediate indebtedness, which included the invisible as well as the tangible elements in international transactions.

Incidental to the controversy between the currency and banking schools of 1830 to 1860 the theory was further elaborated so as to take account of short run complications and of bank deposits as either constituting currency along with gold and banknotes or as contributing to

the efficiency of currency proper. In the course of this controversy most of the present day doctrines with respect to the part played by the credit policy of the central bank and of the banking system as a whole both in disturbing and in restoring equilibrium in international balances were clearly and frequently although somewhat unsystematically presented. Many of the participants in this controversy, including J. S. Mill and Cairnes (*An Examination into the Principles of Currency Involved in the Bank Charter Act of 1844*, Dublin 1854), dealt with the mechanism not as if it were a purely automatic process, the outcome of the unregulated activities of countless individuals pursuing their private gain, but as managed by the Bank of England and elaborated on the need under a system of credit banking of a central agency which should endeavor to foresee and forestall dangerous gold drains. The increasing importance of central banks and of international short term capital movements later resulted in still greater emphasis in the more recent literature on these phases of the mechanism, especially in discussions of short run disturbances and cyclical variations but, with one important exception, in no radical revision of the general doctrine.

Most of the classical economists followed Thornton and Malthus rather than Ricardo in placing great emphasis on the part played by relative changes in price levels in the adjustment of international balances to disturbances resulting from international capital movements. Taussig following a hint of Cairnes further elaborated the theory by distinguishing between the divergent trends of the sectional price levels, i.e. the price levels of internationally traded commodities on the one hand and of domestic commodities on the other. Cairnes argued that the international transfer of gold associated with such disturbances would of itself constitute a transfer of purchasing power, would therefore operate to increase the purchases of foreign goods in the receiving country and to decrease them in the remitting country even in the absence of price changes and would thus lessen the need for price level changes as a part of the mechanism of adjustment. In recent years Bastable, Wicksell and Ohlin have carried this line of argument still further. Wicksell asserted that a sufficient contribution to adjustment would be made in the absence of price level changes by the increased purchases of exportable goods as well as of imports in the receiving country and by the decreased purchases of exportable goods as well as

of imports in the paying country, which would result in each case from the transfer of purchasing power. Ohlin has emphasized the possibility of the transfer of purchasing power otherwise than through gold movements and especially through international shifts of bank balances. This trend marks essentially a return to the conclusions although not necessarily to the analysis of Wheatley and Ricardo. While these writers correct the predominant overemphasis upon the part played by gold movements and direct attention to a neglected phase of the mechanism, their reluctance to attach any weight to price level changes induced by gold movements as a significant part of the mechanism seems unwarranted on either a priori or empirical grounds. These modern modifications of the classical theory have had practical significance in that they have been used to reenforce the presumption already derived by many economists from the classical theory that the transfer problem in connection with reparations was unlikely to prove a serious one.

The dominant form of classical theory of international trade did not posit any simple relationship between general price levels in different countries, even when these were on a common gold standard. Internationally traded commodities, given a common currency, would have maximum differentials in prices in different countries corresponding to the costs of transferring these commodities from the country of export to the country of import. In the absence of transportation costs and tariffs the scales of relative prices of such commodities would approach identity in all countries, even when the currencies were different. But there would be no simple relationship between the prices of particular domestic commodities or the price levels of domestic commodities as a class in different countries; where these are different commodities, direct price comparison is impossible in any case. If the factors of production employed in one country's export industries have high efficiency measured in the monetary value of output as compared to the factors of production employed in other countries' export industries, money wages and other incomes would be comparatively high in such a country and real incomes would also be high if measured in export or import commodities. But the prices of domestic commodities might be comparatively high and real incomes in terms of domestic commodities comparatively low, if the comparative efficiency in their production was low.

Wheatley, Ricardo and in recent years Cassel and other exponents of the purchasing power parity theory have, however, expounded a simpler theory of international price relationships. According to these writers relative trends of price levels in two countries will be inversely proportional to the trends of the rates of exchange of their respective currencies, so as to maintain constancy in the trend of the ratio of general purchasing power of the two currencies in either country multiplied by their exchange ratio. This theory was applied especially to paper currencies, but Cassel admitted that if valid it should hold also for gold standard currencies. Since under the gold standard variations in exchange rates are limited to the narrow range of the gold points, it would follow from this theory that under the gold standard appreciably divergent price level trends in two countries would be impossible. Wheatley and Ricardo admitted of no exception, but Cassel has conceded that the theory of uniform trends or price levels after adjustment for changes in exchange rates would hold only if no disturbing factors such as changes in transportation costs, tariffs or capital movements occurred. There is an element of truth in the theory. If in one country there is an increase in the volume of currency which affects all prices proportionately within that country and if no other change occurs, then that country's currency should fall in value relative to foreign currencies by exactly the degree in which its price level has risen. But even under the gold standard and even if transportation costs are disregarded, there may be divergences in the trend of the general price levels in two countries, if there are changes in the reciprocal demand of these countries for one another's products due to changes either on the demand or on the cost side. There may even be divergent trends of weighted price indices in the two countries for internationally traded commodities, if the weights used correspond to the relative importance of the different commodities in the respective countries and if these weights differ for the two countries. During a period, however, when the dominant factor in the situation is the variation in the issue of inconvertible paper money, the purchasing power parity theory in the absence of speculative disturbances often gives a fairly satisfactory explanation of the actual course of events. Under the gold standard dependence on a common monetary standard tends to result in a substantial similarity of trend of price levels and especially of prices of internationally traded

commodities in different countries. But there is no simple relationship either between the absolute levels or between the trends of the price levels of domestic commodities in different countries, whether these have paper currencies or different metallic currencies or are all on the gold standard.

The chief difference between the mechanism of adjustment of international balances under the gold standard and under the paper standard is the greater importance under the latter of variations in the exchange rates. The role in the equilibrating mechanism played under the gold standard by exchange rates, gold movements and changes in relative price levels must under the paper standard be carried out by exchange rate changes alone. The contrast, however, is less sharp in this connection between the mechanism under a managed gold standard and that under a paper standard. Under a paper standard price levels are under the control of the paper money and bank credit issuing agencies more completely than under the gold standard. These agencies can keep price levels as a whole substantially free from external influence and can thus throw the main burden of international adjustment on the exchange rates. But the disparity in terms of their own currency which may thus develop between the prices of international and of domestic commodities will ordinarily result in considerable pressure on these agencies to make the price level move much as it would under the gold standard. Even in such a case, however, the movement of prices is the result of deliberate central action and not, as under the pure gold standard, of the automatic response of countless individuals to changes of external origin. No detailed theory of mechanism under the paper standard analogous to that under the pure gold standard can be developed on a priori grounds because of the presence in the former and the absence in the latter of a deliberate and centralized control over the amount of circulating media.

The theory of international trade is almost invariably expounded in terms of free competition within and between countries. The growth of monopolization of industry and the development of government trading, most notably and completely in Soviet Russia but also in other important instances, tend to lessen the applicability of this theory to the actual course of post-war trade. But complete commodity monopolies in world markets are still rare, and trade under partial monopoly conditions is qualitatively little dif-

ferent from trade under perfect competition. Where governments trade as units on behalf of their nationals they can follow other principles than those of buying in the cheapest and selling in the dearest markets and of specialization in accordance with comparative costs, and they may pursue political as well as economic objectives. It is impossible to generalize about such cases, and the only procedure available is to observe the methods and the objectives of the particular policy followed and to compare its results with those which could reasonably have been expected to flow from trade conducted by private enterprise in pursuit of private gain.

INTERNATIONAL WATERWAYS. Under Roman law a navigable stream was a public passage way free for the navigation of all citizens of Rome or of its subjects or allies. The public law of the Holy Roman Empire, which applied in central Europe, contained the same principle. In both empires this question was looked upon as one of internal public law, but the wide extent of their territories and the universality of their claims to dominion made for a general acceptance of the rule of freedom of navigation and commerce over great rivers, such as the Danube, the Rhine and the Oder, which persisted after the political situation had been changed by the emergence of national states, like France, and by the increasing independence of the great princes in Germany.

Freedom of commerce and of navigation was frequently recognized in legal documents of the empire and was expressly declared to be an inter-

national right in treaties affecting the Rhine and German rivers, notably the treaties of Westphalia at the close of the Thirty Years' War. This legal freedom of commerce and of navigation was limited, however, by the rights of riparian lords, of cities and of boatmen's associations. In theory the right of princes and cities to take tolls rested on ancient custom or grant from the empire, but the existence of many illegal tolls is evidenced by provisions in the early treaties requiring their abolition. The tolls were established theoretically as a grant by the empire to provide a means of protection to boatmen and merchants and for upkeep of towpaths and channels, but they were in fact a heavy burden on the navigation of the river and a source of great profit to the territorial princes. The monopoly of navigation on various stretches of the river by guilds of boatmen, the right of merchants in the riparian cities to demand compulsory unloading of passing cargoes and the heavy passage tolls of the riparian princes, made worse by the delays at the numerous toll stations, continued in effect to the time of the French Revolution. The advantage to the princes and to their subjects which came from attracting traffic to the river was the only check on these obstructions. It led on the Rhine to a sort of joint control by the four great Rhine princes. Recognizing the common interest, they agreed with one another to protect traveling merchants who had paid the tolls and to make the examination of cargoes for toll purposes as prompt as possible. A committee was to meet yearly to discuss navigation questions and to advise on improvements on the river and on police measures. While this ameliorated the situation it did not free the growing commerce of Europe from hampering restrictions.

The rise of independent states and the consequent development of international law does not appear to have changed the situation substantially. Early writers on international law accept the existing tolls and ancient privileges but maintain the right of free passage for boats and goods. Grotius argues that no toll can be taken for the exercise of this common right except as a recompense for the cost of protection of travelers and maintenance of the river. Others, however, developed a theory that the law of nature did not permit free passage of goods and that such passage could be claimed by merchants and boatmen of other countries only as a result of contract.

A striking claim for river freedom was made in the eighteenth century. The Treaty of Mün-

ster gave the Dutch the privilege of closing the Scheldt, the estuary which led from the sea to Antwerp, and that closure was strictly maintained. The emperor Joseph II as lord of the Low Countries tried to break the Dutch hold on the river on the ground that the treaty throttled the trade of the city of Antwerp. Through the mediation of France, however, the treaty right was affirmed. Seven years later France, then a republic, took a contrary view. The French army occupied Antwerp and the French Executive Council declared the river open on the ground of natural justice, but only for riparian countries.

After the decree was confirmed by a treaty between France and Holland the French government proceeded to extend by treaty the principle to the Rhine, on which it was a riparian, and proposed that the Holy Roman Empire should agree to apply to the Danube the rule of freedom of navigation for French vessels; but this was not accepted by the empire. As French power was extended on the Rhine, the republic succeeded by the agreement of 1804 in abolishing the guilds and limiting the obstructive rights of the cities to the right of transfer of cargo at Mainz and Cologne. In effect a monopoly of navigation was secured in reorganized government regulated associations on the upper and lower river, into which, however, any qualified boatman might be admitted. Tolls were fixed and could not be increased without the consent of both parties; toll stations were limited in number, but the principle of profit was not abandoned. France and the German princes divided the surplus revenue. The treaty is famous in river history for establishing the first organized system of international river control. It was administered by a director general, appointed jointly by the French government and the archbishop of Cologne, acting for the German Rhine princes. The director general had supervision over the towpaths and the policing of navigation. The cost of maintenance of towpaths was made a charge on the toll revenue. Judicial unity was sought by the establishment of an appeal Board of Jurists, made up of one representative for each party to the treaty and the director general; to this board could be carried rulings of the toll officials involving tolls or infractions of regulations. Such was the situation at the close of the Napoleonic wars. By the Peace of Paris in 1814 the allies went a step beyond the opinions and practise of the French government by declaring the freedom of the Rhine "so that it can be interdicted to no one" and engaged the congress

which was to settle the affairs of Europe to extend the same principle to other rivers.

The Congress of Vienna went on record in favor of freedom of navigation and confided to the riparian states on each stream the duty of organizing its administration as an international system. The principles which were to govern Rhine regulations were laid down in some detail. As a compromise between the general interest in freedom of navigation and the territorial rights of individual states a central commission was set up to make rules and regulations for the navigation of the river and to keep it free of hindrances to navigation, but it was without power to do more than propose the regulations to the states. Compromise again appears in the Rhine courts which were to settle disputes over the tolls and to judge infractions of the regulations. The judges were appointed by the local authorities, but they took an oath to observe the treaty and regulations; and an appeal was allowed from their decisions to the Central Commission itself. As an alternative an appeal could be taken to a higher court of the local state. The number of toll stations and the total tolls were also fixed in the treaty.

It was not until 1831 that the Rhine Treaty was accepted and the commission set up. It functioned well, with certain liberalizing modifications made in 1868 by the Treaty of Mannheim, until the World War. A similar system was applied on the Elbe and on other European rivers and was enacted for the Congo by the Berlin Conference of 1885, but an administrative organ was never set up on the African river. The system was able to deal with the changes resulting from the replacement of boats moved by sail and horse power by steamboats and long fleets of barges towed by powerful tugs. It was adjusted to the commercial transformation by which boats owned by individuals gave way to great fleets of steamers and barges owned by large corporations, which controlled the navigation on the river. It preserved the navigability of the channel in the common interest against threatened interference by bridges and power works. The system of tolls was formally abolished in 1868 and complete freedom of navigation assured to non-riparian boats. Other less important international rivers in Europe were regulated by treaty between the riparian powers, assuring free navigation for riparians and freedom of commerce but without any elaborate machinery for enforcement. Thus freedom of navigation was in principle declared the rule for all

international rivers on the continent, with control over the navigation and detailed regulation vested in the riparian states, which were recognized as having a primary interest.

A notable exception to the principle of riparian control was the European Commission of the Danube created by the Treaty of Paris of 1856 at the end of the Crimean War. The commission was intended at first as a temporary expedient. The permanent control of the river was to be in a riparian commission following the normal European system. There was, however, an urgent need of improvements to deepen the water in the mouth of the river. The powers did not trust Turkey, so the European Commission was set up to do the work and authorized to fix tolls to cover the cost. The commission was composed of members appointed by the great powers, except Russia, and Turkey as sole riparian. It was expected that the commission would have completed its labors in two years, but the weakness and inefficiency of Turkey led to its continuation and to the great increase of its power, so that it finally became the authority which made the rules of navigation on the stretch within its jurisdiction and enforced them through its own administrative officers, who had the power of levying fines. Russia as a great power and Rumania as riparian were later admitted. Guard boats of the great powers represented on the commission were authorized to act against ships flying their flags, as far as the jurisdiction of the commission extended, although it was all on Turkish, subsequently Rumanian, territory. That jurisdiction was extended to the cities on the river to which the seagoing vessels ascended, so that the commission, at first a mere engineering organization on the Danube delta, came to have a very wide authority independent of the riparian state over works and the navigation in the river up to the great ports. On the upper river no plan for a regulating commission proved successful because of political difficulties, but navigation was free to all riparian countries under treaties and in the lower river navigation was free to all flags.

On the European rivers it was evident that there must be control of works interfering with navigation. This was taken care of in the Rhine Treaty by requiring the consent of the Central Commission for the construction of bridges, dams and other works which might hamper shipping. Planning and building works of improvement on the river were left to the riparian states, which defrayed the cost, except in the

notable case of the Danube Commission and in the instance where improvements at the famous Iron Gates, a series of rapids in the same river, were confided to Austria-Hungary, which was permitted to charge tolls to recoup the cost. Normally, however, if the river was improved no extra charge could be made on passing boats. On the Rhine after 1868 all vessels could profit without charge by the expensive works which deepened and rectified the channel.

On the American continents the development followed another course. The great South American rivers were opened to the navigation of all flags by treaties and by unilateral declaration of the individual governments. Notably Brazil proclaimed the freedom of navigation on the Amazon, which is a means of communication from Peru and Bolivia to the Atlantic. There was no necessity on these wide or comparatively little frequented streams for the joint regulation of navigation and for the creation of an organ for quick adaptation of the rules to new conditions arising on the river.

In North America the United States was in the beginning of its history vitally interested in the free navigation of rivers. Both the St. Lawrence and the Mississippi were outlets for great interior American territories. The mouths of both rivers were held by foreign states and the American government was always most insistent on the principle of freedom of navigation for the upper riparians down to the sea and the right to use the port of New Orleans, without which freedom of navigation was of little value. The necessity of freeing the trade of the west had more influence than the acquisition of new territory in leading to the Louisiana Purchase, which put the whole Mississippi valley under the American flag. On the St. Lawrence and other rivers between the two countries the United States and Canada were able to arrive by treaty at a satisfactory arrangement of their disputes over navigation. There has been no necessity for the kind of administration developed in Europe to regulate vessels using the waterway, but the problem of interference with navigation by works in the river caused the creation in 1909 of an international commission, more properly a sort of administrative international court, whose consent is required for the construction of any dams or other obstructions in waterways common to the two countries or for the taking of water from them.

The peace conference after the World War emphasized world wide as against riparian rights

in European rivers, being principally concerned with the great streams flowing in part through the territory of the central empires. Several of the new states created at Versailles—Czechoslovakia, Hungary, Austria—had no seaports but were upper riparians on navigable rivers. France had come back to the Rhine as an upper riparian after having been off the river since 1870. There is also the possibility of the development by the building of connecting canals of an inland water route from the North Sea to the Black Sea much shorter than the sea route and competing with it. There were therefore strong economic and political reasons for the Allies' insistence on the rights of other than riparian states in the control of the rivers. The treaties of peace declared the central European streams international and open to the commerce of all flags. They changed the principle of Vienna which confided the regulation to the riparians, by putting a strong group of non-riparians on the commission which laid down the river statutes and judged river cases. In no instance were the non-riparians given a majority, but no longer was the administration of the Rhine and the Elbe and the Oder looked on as a matter of local concern. International rivers other than those in central Europe were in general left in control of riparians. In the Commission of the Danube which was created as a result of the conference of Paris the non-riparian interest was represented by members of the European Commission, which was continued minus Russia, Germany, Austria-Hungary and Turkey.

Freedom of navigation of international rivers as part of general freedom of communications and transit is fixed as a principle in the Covenant of the League of Nations and has been included in general treaties which assure to all countries signing them free use of international streams passing through the territory of other signatory countries. Machinery has been set up in the League to facilitate the carrying out of the obligation of free transit. The transit and communications organization of the League consists of a permanent secretariat, an advisory and technical committee which meets about twice a year and a general conference meeting every four years. It thus provides a forum for the discussion of difficulties, and it has provided also a method for settling disputes arising on particular river systems under the treaties governing them. Such a difference may be submitted to the organization, which will then investigate through experts and render an opinion which although not binding

may have very persuasive effects. The judicial system of determining the meaning of treaties set up by the League through the Permanent Court applies here also, and a new legal guaranty of order on European rivers and a protection of rights of navigation and use of waters is contained in the clauses put into the post-war river treaties and into the general convention, permitting appeal to the International Court on the part of any one of the states interested.

While there will always be minor disputes between the nations using the rivers, the administration of the Rhine and the smaller central European streams under the post-war order has offered few serious problems and has worked to the general satisfaction of all. The Danube, however, is a more complex problem. While the revived European Commission and the new international commission, which divide the administration between them, have preserved general freedom of navigation, they have been criticized for their failure to perform some of the functions of construction and improvement assigned to them at Versailles and for postponing repeatedly consideration of difficult problems instead of meeting them at once. Nevertheless, many difficulties have been overcome and substantial results achieved.

Freedom of navigation of international rivers is sometimes treated as a principle of international law, and some authors even extend the principle to national rivers; but in practise there have been no cases where navigation even of an international river has been claimed and permitted as a legal right. The United States endeavored to make the point with Great Britain but encountered stout resistance and finally yielded to settling the dispute by a treaty. In Europe the system of treaties covers all the important rivers, and freedom of navigation of international streams has been accepted "as the public law of Europe." The right of navigation is a custom secured by treaty rather than a principle of international law, and perhaps the best proof of its dependence on convention is in the general treaty of 1921 on navigable waters, by which each signatory grants reciprocally freedom of navigation on the portion of international waterways under its jurisdiction. Even, however, if the principle of law were accepted, it would be necessary to have a regulation in detail, which would be possible only through agreement among the states. On crowded rivers there must be a single set of rules and regulations for navigation effective in the territory of all the riparian

states; there must be found some way of regulating the customs formalities and controlling boatmen on the river. Furthermore the right of passage with vessels and goods would be of little importance without the right to use the ports to which the goods are sent, and this must be secured also by reciprocal treaty regulation. Again, many rivers are broken by rapids and falls around which canals have been constructed. If free navigation of a river is to be a reality, the right to use these canals must be permitted. Even if a rule of law authorized joint use of the stream by the riparians, this right would not extend to works constructed by one of the states on its own territory. In practise on the great waterways of the world canals are made free by treaty.

The custom of freedom of navigation, no matter how well guaranteed by treaties, is likely to break down in time of war. Thus during the World War navigation on the Danube was broken up by active naval operations on the river and by the planting of mines, clear breaches of the Treaty of Berlin. It is very difficult in practise to prevent strong belligerent states from using any force at their disposal to defeat the enemy and to keep naval activity off a river which forms a military line.

National rivers are under the control of the national sovereign, who may permit or refuse navigation by foreign vessels. Several South American countries, some by treaty and some by statute, permit free navigation on their streams. Such statutes may of course be repealed at any time, in which case no government whose subjects have been enjoying privileges under the provision has the right to complain. In China the right to navigate Chinese rivers has been given to foreigners by treaty. There is vigorous opposition on the part of many Chinese to this arrangement, but there is not likely to be any change before there has been a considerable development of Chinese navigation. The Chinese object not only to having foreign vessels on their rivers but also to the unfairness of an arrangement which gives to foreigners a privilege on internal Chinese waters which is not granted to Chinese in the territory of the foreign state.

The principle of the first French Republic that a stream is the common property of all the riparians has been fully accepted in Europe and generally applied in other countries, but this recognition has been limited to use for navigation and extended to non-riparians. Only comparatively recently, as the value of streams as a source of electrical power has increased, has the

community of interests theory been suggested as applying to the use of these streams either for this purpose or for taking water for irrigation or other uses. There are many difficulties inherent in the establishment of electrical works so placed that they will involve more than one country. In 1911 the Institute of International Law, representing the best theory on the subject, prepared a draft convention under which the principle of community of interest was to be applied in respect of all the uses of an international river. The institute, however, was ahead of its time, and even in 1921 at the Conference on International Waterways at Barcelona the governments were able to agree only on a general treaty binding signatory states to permit investigation of conditions on their territory by other signatory states, where necessary, to prepare plans for a development and to enter into negotiations for the execution of a project interesting two or more states. Even this mild attempt at securing unity of development has been ratified by few states. The principle of unity of use of streams has been most fully developed in the Treaty of 1909 in respect to boundary streams between the United States and Canada.

Both as doctrine and as practise the question of the right of an upper riparian state to take water from an international stream to the detriment of a lower state has been contested between the United States and Mexico. The United States as an upper riparian has never admitted the right of its neighbor to prevent the construction of dams and the diversion of water from the Rio Grande and Colorado but has admitted that as a matter of equity and comity the rights of the lower riparian should be considered. In the Convention of 1906 the United States government agreed to assure to Mexico a certain flow of water as a result of the Rio Grande irrigation project, although the government declared expressly that this arrangement was not to be considered as a recognition of any right on the part of Mexico. Authors are divided on the question, many maintaining that one country should not be permitted even by works entirely on its territory to make such use of an international stream that injury results to another riparian without the latter's consent. In deciding disputes between the states in the United States the Supreme Court has applied this theory. Other authors agree that the injured state has no legal right to object, but good neighborliness and comity should lead to respect for its necessities. It is probable that the development will

be in this direction. But the principle of community of use has not behind it the long historic development of the principle of community of navigation.

Freedom of navigation of the great canals which join two seas is more far reaching than freedom of rivers. It is the commerce of the world and not the commerce of a group of riparian states that is affected by transportation through the Suez Canal, the Panama Canal and the Kiel Canal, which unites the North Sea with the Baltic. These canals are open by agreement. The Convention of 1888, signed by the great powers and some of the smaller powers of Europe and revived by the Treaty of Lausanne of 1923, requires that the Suez Canal "shall always be free and open in time of war as in time of peace, to every vessel of commerce or of war, without distinction of flag." The treaties between Great Britain and the United States and between the United States and Panama adopt for the Panama Canal the rule that "the canal shall be free and open to the vessels of commerce and of war of all nations . . . on terms of entire equality." The Kiel Canal, by article 380 of the Treaty of Versailles, "shall be maintained free and open to the vessels of commerce and of war of all nations at peace with Germany on terms of entire equality." The right of use by belligerents of the Suez and Panama canals is regulated, and acts of war in their waters are forbidden. The notion of their neutralization is, however, very limited. The United States while at peace will enforce the neutrality of the Panama Canal but is not barred from preventing its use by an enemy. The Suez Convention binds the European powers and has been applied in several wars to assure equality among the belligerents.

After the World War an attempt was made effectively to internationalize the Dardanelles and the Bosphorus by the Convention of 1923. Demilitarized zones have been established on both sides of these waterways and they are controlled by an international commission under the League of Nations. Turkey holds the permanent presidency of this commission. The straits are to be open to merchantmen and war vessels of all powers in peace or war, except to the enemies of Turkey.

INTERNATIONALISM may be defined as the ideal of an organic, supernational society which would include within itself constituent national societies controlled from above but endowed with independent functions and vitality. Implicit in the ideal is the deeplying presupposition that the process whereby the social unit—within which individuals feel themselves bound by ties of mutual sympathy, common interests and moral obligation—has been gradually enlarged through the course of history is capable of still further expansion. Since the beginning of the modern period the dominant unit of moral and social obligation has been the nation, a grouping bound not only by political allegiance and eco-

nomic interests but also by certain elements of a common culture, usually by a common language and invariably by a common historical background of struggle and achievement. While internationalism aspires to transcend national antagonisms, whether due to geographical or to historical forces, and entails necessarily a genuine limitation of national sovereignty, it assumes the survival of nationality in a modified, regulated form. Essentially institutional in its program and objective in its approach, it is distinguishable from cosmopolitanism, which may be interpreted as a subjective state of mind that grasps the unity of mankind without, however, attempting to solve the relations of the part to the whole.

Despite the violent antagonisms which it has aroused ecclesiastical organization may be said to have been on the whole a powerful influence in the evolution toward internationalism. Although the cosmopolitan tradition inherited by the mediaeval Christian world should be distinguished from internationalism proper, which presupposes the existence of national states, it remains none the less true that the mediaeval church created and conserved in the shadowy structure of the Holy Roman Empire at least the aspiration for an international society. This aspiration, which later European civilization never wholly lost, inspired in the period following the rise of the national state a succession of influential projects which were international in spirit. Sully's project for a federation of Christian princes who would assure peace among themselves and incidentally fight the Turks was followed by William Penn's more sincere version, and by stimulating the more systematic proposals of the abbé de Saint-Pierre and Rousseau for a pacific federation it helped indirectly to form the visionary mind of the czar Alexander and thus to shape the Holy Alliance. These schemes were all confined to Europe and based themselves rather on the fraternity which ought to unite Christian princes than on any democratic conception of human brotherhood.

As an effective force, however, the conception of ties wider than national frontiers was forwarded less by speculation than by the struggles of creeds and classes in the modern world. The wars of religion of the seventeenth century, which divided Europe into a Protestant and a Catholic party, reflected, however broadly, a sense of common interests within the rising mercantile and capitalist class in its struggle with feudalism. The Enlightenment of the eighteenth

century, which freed this new outlook of the middle class from its early theological basis, was cosmopolitan. A lay intelligentsia of writers and scientists was winning for itself in this century a new position of leadership. Experimental science was based from the first on international collaboration and created its own world wide republic of learning. It was an age of cheap and rapid translation; what was written in Paris was printed in English within a few months. The philosophers wrote for mankind. The musicians could defy the legacy of Babel. This cosmopolitan outlook the intellectual and artistic world has never since lost. At a later date German music and philosophy and French painting helped to soften a national feud; while a distinctive national note in art could whet the curiosity and sympathy of the rest of mankind.

Moreover the eighteenth century made the immense intellectual advance of conceiving world history as a single evolutionary process. A generation which had read Volney or Condorcet's stimulating sketch could no longer suppose that nations work out their destiny in isolation. When the Enlightenment became with the French Revolution an "armed doctrine," there resulted at least in the earlier phases of the movement a vast international struggle waged by a class, conscious of a common antagonism to priests and kings and of common interest transcending frontiers. Franklin's epigram, "Where liberty is, there is my country," and Paine's crusading retort, "Where liberty is not, there is mine," sum up its spirit. Theoretical speculations concerning an eventual international federation were in the main hasty improvisations ephemeral in their influence. A striking exception, however, is Kant's *Zum ewigen Frieden*, which still retains its value as a clearly formulated and systematic expression of this early liberal internationalism dedicated to the perpetuation of peace. Although Kant's sketch represented on its formal, constructive side a development of the project of Saint-Pierre, it is significant that in harmony with the rapidly emerging spirit of democracy great emphasis is laid upon the stipulation that every member of the international commonwealth be a republic.

This liberal, revolutionary internationalism giving way for a time to the distorted internationalism imposed by Napoleon produced eventually by way of reaction the Holy Alliance. Not genuinely international, inasmuch as it constituted an extreme repression of nationality, the Holy Alliance was a loose union of Old World

"police" states designed to preserve order on the basis of the dispositions of the Congress of Vienna, to keep the peace and to buttress monarchy, conceived as a divinely appointed institution, against the godless forces of revolution. The just hatred which it aroused among democratic and liberal elements in Europe and America has tended to obscure the immense advance which it represented. After the anarchy of universal war it was the first attempt to base order on the consent of the chief governments of civilization. It conceived of its congresses as quasi-sovereign assemblies entitled to make decisions for the general good; nor was its organized conscience wholly absorbed in combating liberalism and nationalism, for it repressed the slave trade also. Fully recognizing the principle that in any part of the world disturbances, however minor, may become matters of universal concern it represented, albeit with the feudal perversity of an older time, a higher sense of human solidarity than did some of the statesmen who broke away from it. Canning, for example, although in fact he helped the cause of freedom, was in principle looking backward when he invoked the "healthy" rule, "each for himself and the devil take the hindmost." It remains true nevertheless that the identification of world order by the Holy Alliance with the pretensions of "legitimate" dynasties and despotic empires discredited internationalism itself and delayed its advance.

This incarnation of internationalism in a police uniform led to popular reactions in various forms, ranging from nationalist risings to the Monroe Doctrine. One of these, although based on a reading of history as the struggle of classes, was the most uncompromising assertion of an international position yet uttered. Karl Marx through his Hegelian training belonged, as it were under a bar sinister, to Kant's family. The *Communist Manifesto* proclaimed the solidarity in interest and feeling of the toiling masses the world over, regarded national governments and the sentiment of patriotism that they foster as devices of the capitalist ruling class to enslave the proletariat by dividing it and based the modern socialist movement on the watchword "Workers of all lands unite." Victory would mean the abolition of class and therefore the complete unity of mankind. The Socialist International in its first form aimed at this unity through the creation of a world wide party of workers. The fact that it was composed of individual members pledged to a personal allegiance

led, however, to fatal internal dissensions; and therefore when it was later revived as the Second International it was a federation of autonomous national parties, which none the less obeyed the resolutions of its periodical conferences on broad questions of principle and strategy. While recognizing the fact and sentiment of nationality the theorists of the Second International, notably Jean Jaurès, emphasized its cultural aspects, the spiritual heritage which a society based on equality would bring within the grasp of every working citizen. The ethics and to a great extent the actual practise of the movement ranged it in opposition to every form of chauvinism, militarism and imperialism. The duty of a good socialist was to combat the aggressive and acquisitive designs of the ruling class of his own country, trusting to his comrades in other lands to do as much. Socialist parties tried within the limits of their influence to extend their protection to the subject populations of the empire to which they belonged. With international organization, save on this class basis, a logical Marxist was not concerned: that would come with the triumph of the revolution. The World War subjected the Second International to a test which revealed how superficial was its faith in this revolutionary creed; but there were distinguished exceptions, notably the Independent Labour party in Great Britain, the Socialist party in the United States and the Independent Socialist minority in Germany.

A working model of an international socialist federation now exists in the Union of Soviet Socialist Republics. Although it is more highly centralized than any other federation in the world, its component republics in theory are sovereign and enjoy the right of secession. Actually its unity is preserved and internal disputes composed by the tightly disciplined Communist party, which exercises in all of them the dictatorship of the proletariat. However open to criticism in other respects, it has solved successfully the specific problems of nationalism. Russians—Great, Little and White—Tartars, Georgians, Jews and many backward Asiatic peoples enjoy within it complete equality, are helped to preserve their languages and their distinctive cultural traditions and find in the Communist party a ladder which may, in fact does, lead members even of the minor races to positions of the highest influence in the federal government. It is possible moreover to reconcile a considerable measure of national and regional

autonomy with an economic structure that plans and coordinates production, consumption and external trade over the whole of this immense continental area. The theory of the Communists is that as the world revolution spreads other socialist republics will enter this union on the same terms. The U. S. S. R. is not a Russian state: it is an international society and a rival to the League of Nations.

After the disappearance of the Holy Alliance its place throughout the latter part of the nineteenth century and the pre-war years of the twentieth was partially filled by the concert of Europe. This loose association of great powers had no permanent organization and functioned only in emergencies—arising chiefly out of the Eastern Question, in which lay through three generations the chief risk of war in the Old World. Preoccupied with the possible break up of the Ottoman Empire, the Concert of Powers alternated between the imposition of inadequate reforms and the repression of nationalist insurgency. It had no rigid legitimist principles, such as those of the Holy Alliance; if its bias was conservative leading it on occasion, as in Crete, to check rebellion by armed force, it was influenced chiefly by the dread that any disturbance of the status quo would precipitate a major war. Although resorting now and then to formal conferences it reached most of its decisions through ordinary diplomatic channels. Its prestige served as a check upon antisocial ambitions and kept alive a certain faith in the authority of international opinion and the possibility of united international action, although its actual constructive achievements, such as the regulation of the Danube as a free waterway and the creation of an international gendarmery in Macedonia, were few in number. Its work in the Near East served in certain respects as a model in the settlement of the somewhat analogous Moroccan and Chinese questions. Within its limited range of action it constituted a nucleus that might have developed into a kind of oligarchical international authority. It had behind it, however, no body of popular opinion, no proclaimed principles, no prophet who might have done for it what Wilson did for the League of Nations. Essentially an improvisation, it left intact the ultimate right of a great power to do what seemed good in its own eyes. But its main defect was insincerity. Throughout its long career of spasmodic service to the cause of peace the powers that composed it were rendering international cooperation in the long run impossible

by their competitive armaments and the alliances that ranged them in two camps more permanent and better knit for action than the concert itself. The Great War was an outcome of this very Near Eastern question and of the failure of Sir Edward Grey to mobilize the concert to regulate it.

The collapse of the concert in 1914 set the central problem of internationalism which the world has since struggled to solve. The value of the ad hoc conference was still recognized, but it became increasingly apparent that improvisation on the eve of an emergency was not enough and that a permanent organization was necessary. Moreover since any major disturbance might lead to a world war, it was unrealistic to confine the new concert to Europe or to hope that disputants in the hot hour of anger would submit themselves to the judgment of their peers. If confidence was to prevail, if the old competitive armaments were to be avoided, each nation must have from its neighbors a pledge that they would follow some recognized pacific procedure. Finally, if in spite of all an aggressive power should break its bond, the rest of the world must be mobilized to support the innocent victim.

Out of such reasoning grew the League of Nations. Primarily an international organization to enforce peace, the League has exerted an unprecedented stimulus on the development of internationalism. With astonishing suddenness a world which hitherto had organized itself permanently for international ends only in such minor fields as the postal and quarantine services provided itself with an organization which unfriendly critics could describe as a superstate or a world government. The inaccuracy of this description is evident from the fact that member states seem to surrender nothing of their sovereignty, save in so far as every treaty is a voluntary restriction of one's supposed right to do as one pleases. No subject or field of action is abandoned by the members and made over, as in a federation, to the League. It can take no action and impose nothing in the nature of legislation, save with the consent of every member of its Council or Assembly. None the less, if and when its Council acts—as, for example, to impose sanctions—every member of the League is involved in the consequences. A pledge once voluntarily given can be enforced. A disputant moreover loses his vote for the time being in the Council and cannot invoke the rule of unanimity to stop its action. In these respects the League does involve a real restriction of sovereignty. Again, in

theory, if its machinery of conciliation and arbitration worked reliably, the great powers would surrender the advantage of negotiation inherent in the possession of unrestrained force.

It seems probable in retrospect that the founders of the League went at once too far and too fast and yet not far enough. The question arises whether perhaps they conceived their problem too simply as the abolition of war. The ultimate cause of war is the survival of sovereign national states which claim the right to exert their will for their own ends subject to no judge save themselves. But sovereignty can hardly be limited in one particular if it retains Old World nationalist habits of action and thought over the rest of its field. While on paper the League is well equipped with all the powers necessary to prevent or stop the physical act of war, it lacks the means to redress the grievances or meet the needs that may drive a wronged or ambitious nation into war—pressure of population, the need of markets, the lack of raw materials, the suppression of nationality. With none of these can the League deal directly, for all of them belong to the sphere of domestic jurisdiction, which it must not invade. It has the power to stop war, but it lacks the ability to bring about by peaceful means the changes which desperate nations attempt by violence to hasten.

Peace, in other words, is but a single aspect, a function, of internationalism. It cannot be insured without an advance into forbidden fields—above all into the economic field—which seem at first glance only remotely involved. So much indeed the League seemed to realize as soon as it began to function. It has discussed tariffs, the gold standard and the overproduction of coal, but always on the understanding that it has neither the intention nor the right to promote action in the sense of the findings of its commissions and that it contemplates no modification of national sovereignty such as would permit of habitual, organized cooperation in the economic field and no common action capable in the last resort, in case of sufficient gravity, of overriding the will of obstructive states.

And yet the world in the last two generations has become a single economic unit. The annihilation of distance by modern means of communication was the first step in this evolution. The next was the development of machinery incessantly demanding a market for its ever rising flood of products. Money and capital have become as mobile as goods, traveling by cablegram across frontiers with baffling rapidity. In-

vestment knows no patriotism; whole countries or their major industries at least may pass in a few years into foreign ownership. The collapse of a Viennese bank may cause in London first a financial and then a political crisis. In the eighteenth century two magistrates strolled round the market place of each little country town in England and fixed the price of wheat. Today it has a world price, which shifts as a few cosmopolitan dealers study the cablegrams that report on harvests and the movements of ships from Winnipeg to Bombay and from Buenos Aires to Odessa. Gold alters its purchasing power as bullion is shipped from Paris to New York. The level of the gold reserves in the vaults of Wall Street may determine the price at which the Indian peasant can sell his rice and with it his ability to pay taxes, rents and usury, on which again his contentment and political loyalty are contingent. A speculative boom in New York followed by a sharp contraction may start a slump that counts its unemployed victims by twenty-five millions the world over. In a word, our political structure no longer answers the economic realities. National sovereignty with its restricted territory was an obsolescent arrangement in the days of sailing ships; the airplane and wireless telegraphy have made of it a solecism.

The World War drove a large part of the world to the perception that some measure of international political organization was necessary. The question now arises whether the world wide depression will make it apparent that economic anarchy is no less devastating and that tariffs, currency and the price level are matters of vital concern calling urgently for international planning by a permanent international organization. If such controls were instituted, the purely political and military problems which concert and League have sought to solve would be immeasurably eased. Thought and sentiment would adjust themselves to the wider horizon. The League or whatever organization may replace or supplement it would gain a new prestige and power. in proportion as it confers benefits it may dispense with coercion: the establishment of economic stability would obviate the necessity for sanctions, since an offending state could be threatened with exclusion from economic privileges and advantages. Frontiers under such a regime would lose much of their importance, and territorial changes would be easier to effect. Nationality in such a world would retain and might even deepen its cultural significance. The

nation state, ceasing to act beyond its frontiers with fleets and armies and admitting a measure of regulation over its economic policies, would work out the more intensively its distinctive conception of social life.

A realistic thinker, while admitting the trend of economic development toward internationalism, will not underrate the obstacles. It may be that machinery has outpaced intellectual growth and that obsolete habits of thought and archaic emotional associations will continue to forestall rational attempts to amend overrigid constitutions. More formidable still is the opposition of interests which rely on national diplomacy and armaments for furthering or defending their economic pursuits abroad. Again, one may doubt whether collaboration is feasible among states, some of which are democratic, some Fascist, some communist. Kant admitted to his international federation only republics, Wilson wished to exclude autocracies, Marx and Lenin welcomed only the classless state. But despite the difficulties inherent in the task new organs of international direction and control must somehow be evolved to keep pace with the triumphs of mechanical efficiency.

INTERNMENT. See ENEMY ALIEN; NEUTRALITY.

INTERPELLATION. An interpellation is a demand addressed by a member of parliament to a minister for a public discussion on some definite subject which may relate to the general policy of the government or to some question of detail. Originally designed to elicit information and to serve as the text for a clarifying debate, the interpellation has become one of the most important means by which legislative control of the executive is made effective under the cabinet system of government. While it is not used in England, where the cabinet is interrogated through the written question, which does not of itself lead to debate and a vote, the interpellation has become rather generally accepted on the continent as a necessary accompaniment of ministerial responsibility.

It has been most elaborately developed in French parliamentary procedure and is used much more frequently in France than in other countries. Although a procedure resembling the interpellation was adopted by the Constituent Assembly in 1791, it seems to have been abandoned within a few years. The right of interpellation was definitely established in the French Chamber in 1831 without any change in the written rules of the Chamber but merely as a logical corollary to responsible government. With the coup d'état of 1852 the right was suppressed along with the parliamentary control of the executive and was reestablished partially in 1867 and entirely in 1869 with the return to responsible cabinet government.

The French parliament uses both oral and written questions as well as the interpellation. The former, which are rarely used, can be asked only if the minister consents; they must be asked at the close of a sitting and not more than two questions are permitted at one sitting. The deputy is allowed fifteen minutes in which to present his question and the incident is closed with the reply of the minister, except that the deputy may be given five minutes of rebuttal. No other speakers are permitted. Written questions are

very numerous in the Chamber of Deputies. Within eight days after they are submitted to the assembly they must be printed in the *Journal officiel* together with the answer of the minister, although the latter may consist merely of a statement that for reasons of public policy the minister cannot reply or that he requires more time in which to assemble the material for a reply. Written questions do not have much connection with parliamentary control of the executive but are used primarily to attract attention to a deputy, to his public spirited curiosity and to his concern for certain interests.

Oral and written questions are thus unimportant in France, because interpellations occupy the center of the parliamentary stage. The interpellation is a request for information which the government cannot ignore. The demand is made in writing to the president of the assembly, who reads it to the assembly. A member of the government suggests a date on which the ministry will reply and the assembly then fixes a date without debate, although the author of the interpellation may be allowed five minutes in which to reply to the government. The discussion of the motion to fix a day cannot, at least in theory, go to the merits of the subject; but the vote is politically important, for the government may fall if it puts a question of confidence and is not permitted to have its way in respect of indefinite postponement or the selection of a date satisfactory to it. Interpellations relating to internal affairs cannot be postponed for more than one month, but those relating to foreign affairs may be postponed indefinitely. A strong ministry can force the indefinite postponement of embarrassing interpellations; weak ministries must consent to discussions which they wish to avoid.

On the date set the author is allowed one hour in which to present his interpellation. The minister replies and the author is then allowed priority in answering. After one deputy has spoken, closure may be applied; but usually the debate is permitted to proceed. It is closed by a motion to pass to the order of the day, which may be either *pur et simple* or *motivé*. The former, which may be moved verbally and has priority, expresses neither approval nor disapproval of the government. If such a motion is not made or is defeated, the assembly is usually called upon to choose between several orders which are *motivés*, or qualified by some expression of censure or praise of the government. The various motions are adroitly phrased so that they will isolate particular issues and will serve to catch the greatest

number of deputies. The question of priority between the various motions is determined by the assembly. Where the order of the day *pur et simple* is not proposed or is defeated and where the issue is very complicated, a motion to submit the question to one of the standing committees or to a special commission may be made and has priority over the qualified orders. Where the order finally approved by the assembly is obviously contrary to the tacit or expressed wish of the government or is a serious criticism of its policy, the government may resign.

With a general debate on the various motions, with a vote on which order shall have priority, with a vote on the order selected and with explanations of individual votes under a five-minute rule, the discussion of interpellations can manifestly consume a great deal of time. Complaints of the waste of time are frequent. The ministry presided over by Méline from 1896 to 1898 replied to more than two hundred interpellations. The prime minister told the Chamber of Deputies on July 12, 1909, that there had been 293 interpellations besides 76 questions in three years of that legislature. Nor, save under the Poincaré Ministry of National Union in 1926, have recent chambers been less inquiring. The ordinary session of 1929 (January 9 to July 26) and the extraordinary session of the same year (October 22 to December 29) devoted 28 and 18 percent respectively of their time to interpellations. The extraordinary session is for budget purposes; and since it concentrates on fiscal matters, interpellations are not so frequent. French ministers reply to interpellations in the Senate as well as the Chamber, but the upper house does not demand as many debates as the lower.

Interpellations cover all sorts of subjects. Petty incidents relating to the local police or insignificant functionaries, the sermon of a country curé, municipal activities, lectures of university professors—on such minor matters ministers have had to consent to be interpellated. Even when conditions are most favorable for the cabinet, interpellations put a tremendous drain on ministerial strength and time. On the other hand, it is the business of a parliamentary body to inform itself as to what the executive is doing and to exert control when control is needed. Criticism of the French machinery therefore should be directed to the manner in which the machinery functions and not to the theory which underlies it.

In continental countries, although procedure

in general follows the French model, interpellations are relatively less important. Furthermore, while in France the right to present questions and interpellations belongs to every individual member, in many countries the signature of a certain minimum number of members is required. In France, partly because the legislature exercises a greater supervision over the details of executive action and partly because the highly centralized administrative system broadens the range of subjects which are of interest to the interpellators, the device is more frequently used, more occasionally abused and always more discussed. To this result the amorphous character of French political parties and the instability of cabinets have contributed. It is not without interest, however, that half of the eighty odd cabinets under the Third Republic have resigned because of the general political situation or for other reasons which were unconnected with adverse votes in the Chamber of Deputies. Interpellations, however, hold the executive to accountability even though the *méfiance* of the Chamber may not be formally expressed.

INTERSTATE COMMERCE

UNITED STATES. The relations of government to trade and transportation are sufficiently difficult in a unitary state. The complications of a federal state accentuate the difficulties. In the United States these difficulties are implicit in the concise phraseology of article I, section 8, paragraph 3 of the constitution: "The Congress shall have Power . . . to regulate Commerce with foreign Nations and among the several States, and with the Indian Tribes." In the beginning, however, were not the words but the warm and lively issues which engendered them.

The clause was conceived as a means of composing the commercial rivalries among the states created by the revolution. Beginning in 1784 protective tariffs were enacted by New England and most of the Middle States, the burden of which fell chiefly on the consuming states with a less flourishing foreign trade. Additional tribute was exacted from the coasting trade, notably by New York, through the imposition of clearance fees. Madison drew a classic picture of "New Jersey, placed between Philadelphia and New York, . . . likened to a cask tapped at both ends; and North Carolina, between Virginia and South Carolina, to a patient bleeding at both arms." Retaliatory measures invited attacks and reprisals, with the inevitable devastating consequences which experience with international trade feuds since the World War has made all too vividly clear. New Jersey and Delaware adopted a contrary expedient, the establishment of free ports, and thereby weakened the resistance of the states as a whole to the discriminatory treatment accorded American shipping by Great Britain, France and Spain. For the fledgling states the constitution and the commerce clause in particular were expected to afford relief and stability.

Continuously from its adoption the commerce clause has been the vehicle for settling dominant issues of national economy as well as of politics. The legal form which these problems have most persistently assumed reflects the historical basis for the grant of power to Congress. With increasing frequency courts have been called upon to determine the scope of authority of the individual states over activities not isolated within the boundaries of a single state.

The question first came before the Supreme Court in *Gibbons v. Ogden* [22 U. S. 1 (1824)]. Speaking for the court Chief Justice Marshall held invalid a New York law granting to Livingston and Fulton the exclusive privilege of navigating the waters of that state by steamboat and sustained the right of competitors to navigate between New York and New Jersey under a coasting license sanctioned by an act of Congress of 1793. The effect upon commerce was immediate and far reaching. In New York as well as in several other states which had granted similar monopolies the number of steamboats in service greatly increased, with an attendant sharp reduction in fares. The legal import of the decision is enveloped in considerable fog. The case is voluminously cited for the broad doctrine that power over interstate commerce is

confided by the constitution "exclusively" to Congress. This interpretation neglects the important ingredient, relied on by counsel and court, of a conflict between state and federal statutes affecting the same subject. Nor did the decision in the absence of control by Congress deter states from granting monopolies of interstate ferriage, of land transportation and later of telegraphic communication. It has been suggested plausibly that at the time the power of Congress over interstate transportation was conceived to embrace only navigation. But this limitation merely expresses evanescent imagination. In 1866 Congress ended the grant of monopoly of railroad and telegraph service between states.

During the quarter of a century following *Gibbons v. Ogden* the meaning of the commerce clause became the sport of confusing debate. The conflict without was reflected within the Supreme Court, and differences among the judges fostered the conflict. Some of the justices rested approval of state action upon subtle distinctions regarding the true aim of contested legislation: a regulation of commerce was invalid, while a regulation of health or safety was permitted, although no practical difference was discernible to an intelligence not steeped in the sophistications of legal dialectic. Other justices, defining powers according to their consequences, insisted that the states regulated commerce when they affected it. But these judicial pragmatists differed among themselves as to the constitutionality of such regulation.

These doctrinal conflicts were composed by events, not by the harmonics of disputation. The development of new modes of transportation provoked increasing exertion of state power and gave rise to new controversies over interstate commerce. The struggle between steamboat and railroad interests for dominance in transportation was brought into focus in the suit by Pennsylvania [Pennsylvania v. Wheeling etc. Bridge Co., 54 U. S. 518 (1851)] to enjoin the maintenance of a bridge across the Ohio River, the construction of which had been authorized by Virginia, on the ground that it would impede navigation to Pittsburgh. During this period also several instances of social legislation were forced to run the gauntlet of the commerce clause. Some were sustained: a New York law requiring masters of incoming vessels to furnish information concerning passengers and laws of three New England states prohibiting the sale without a license of liquor brought in from another state. But a Massachusetts measure impos-

ing a tax on incoming vessels for each passenger, although designated a health law, was held invalid by a sharply divided court. Behind these legal controversies, often sufficiently heated, loomed the burning issue of slavery. A number of southern states had passed laws to exclude free Negro laborers. The relevance of the decision holding the Massachusetts immigration law invalid was apparent to press and public no less than to court and counsel.

Only an awareness of the issues which lay beneath the surface of these cases and of the tenuous and frequently scholastic reasoning by which they were formally decided can reveal the full meaning of *Cooley v. Board of Wardens of Port of Philadelphia* [53 U. S. 299 (1851)]. Succinctly stated the doctrine is that over subjects of commerce which are "in their nature national, or admit only of one uniform system, or plan of regulation" Congress alone may legislate, while over subjects of commerce concerning which there is a "superior fitness and propriety, not to say absolute necessity, of different systems of regulation" state legislation is valid until supplanted by Congress. This decision afforded a candid basis for sustaining state regulations of interstate commerce and as frankly made the determination in each case depend upon judgment and judgment by a majority of the court as to the propriety of the regulation. By making the question of constitutionality turn not upon abstract notions regarding the nature of state powers but upon their concrete and multifarious applications the decision in the *Cooley* case shifted the center of attention to actualities in the disposition of questions under the commerce clause. Thus even in local matters state regulation becomes invalid if unduly burdensome to interstate commerce, while even commerce national in character may be subjected to state regulation if the effect is "remote," "indirect" or "incidental." These are questions of reasonableness and therefore become matters of degree, of more or less, depending for their adjustment not upon tall talk, upon resounding generalities, but upon the relevant facts concerning the necessity or appropriateness of the challenged regulation, the local benefits to be secured and the countervailing cost or inconvenience to interstate commerce. So essential are these specific justifications or handicaps that the same statute which has withstood a blanket charge of "burdening" interstate commerce may succumb before the shrapnel of facts and figures [compare *Southern Ry. Co.*

v. King, 217 U. S. 524 (1910) with *Seaboard Airline Ry. v. Blackwell*, 244 U. S. 310 (1917)]. Indeed more recently the Supreme Court has been disinclined to decide at all unless the record adequately discloses the elements of the specific situation. If the pertinent data concerning local needs and the degree of interference with interstate commerce are lacking, it is ill advised to sustain or to invalidate local control. There is available the sensible procedural device of remanding the case to the lower court for the necessary findings of fact [*Hammond v. Schappi Bus Line*, 275 U. S. 164 (1927)].

The process of adjusting the interacting areas of federal and state authority over interstate commerce testifies to the free play left by the framers of the constitution to judicial and political construction of that document. In this field certainly constitutional adjudication is largely borne on the tide of circumstance. Matters which once were within state competence may be withdrawn: the power of a state to prohibit discriminatory interstate rates was not denied until 1886, in *Wabash, St. L. & Pac. Ry. v. Illinois* (118 U. S. 557)—a decision which precipitated the passage of the Interstate Commerce Act in 1887. Yet in the absence of congressional action a large measure of authority reposes in the states to satisfy needs for which a uniform regime is not required. The issue here is not whether federal action would be preferable to state but whether state action or none at all is to be preferred [*Minnesota Rate Cases*, 230 U. S. 352, 402 (1913)]. Even over matters intimately affecting interstate carriers themselves, such as quarantine and inspection, wharfage charges, pilotage, the improvement of rivers and harbors, the construction of dams and bridges, the misconduct or defaults of carriers, the states have been allowed to legislate until Congress has moved. Again, states may enforce social policies directed not at the carriers but at articles of commerce which a state considers socially injurious. In enforcing such local policies the states encountered the "original package" doctrine, one of the most beclouded and casuistic conceptions of American constitutional law. Shorn of its qualifications and complexities it means that articles transported from another state are immune from state regulation so long as they remain in their original packages or have not been resold locally. Obviously this doctrine opens up broad avenues of evasion of state policies through the shipment of proscribed articles from out of state sellers to local con-

sumers. The main doctrine therefore brought its confining counterdoctrines. In the first place, noxious articles were deemed outside its sway—state policy in part determining what is to be treated as noxious. Thus articles fraudulently misbranded or unfit for consumption may be excluded upon arrival. In the second place, Congress by its own legislation may complement state action in order to achieve state policy. In practical terms, the allowable range of state power may be merely power on paper unless effectuated by the control of Congress over shipments into the state. The best known instance of this collaborative effort is the Webb-Kenyon Act of 1913 allowing state prohibition laws to apply to liquor upon its arrival in the state. The same expedient has been applied to the undesired introduction into states of such diverse products as food, explosives and plants. The possibilities of the device in the economic field are suggested by the Hawes-Cooper Act of 1929, effective January, 1934, which by applying the same principle to interstate shipments of convict made goods permits the operation of what are in effect state antidumping laws. If frustration of state policy is to be prevented effectively, however, this scheme is always open to two further difficulties, one legal, the other practical. Although the validity of state action under a Webb-Kenyon Act is established, there remains in specific instances the preliminary question of the validity of the congressional act itself as a genuine regulation of commerce. Thus, may Congress protect the industrial standards of a state by authorizing the exclusion of goods manufactured in states maintaining lower standards? By the logic of analogies there should be no doubt. But the odd member of the Supreme Court has from time to time been singularly fertile and effective in the invention of doubts. Moreover enforcement by the states of policies so easily defeated by inroads from other states may require more and better equipped officials.

Legal doctrine has likewise accommodated itself to the demands of the expanding national network of economic forces. If congressional action may invalidate state regulation of interstate commerce it may also invalidate state regulations which had theretofore not been banned by the commerce clause. In its earliest and simplest form this principle derives from *Gibbons v. Ogden* and is merely the rule that a state law must yield to a federal law dealing with interstate commerce if the two are "in conflict."

Frequently, however, there is no explicit conflict between the two. In action they may not move in overlapping spheres. Yet the efficient operation of the federal law may depend upon its supersession of the state enactment. A federal safety appliance law describing requirements for railroads engaged in interstate commerce must apply, if it is to be efficacious, to cars of the railroad even though they are used solely in intrastate commerce. Where Congress has manifested an intention "to occupy the field," so runs the conventional formulation for these adjustments, state authority in that field must give way. This is of course a figurative field, and merely the compendious expression of the court's sense of policy. "The intention of Congress" not infrequently is non-existent or too obscure to be discovered. Here no less than in cases where Congress has not acted the court not only does but must exercise a practical judgment. Its chief applications are evoked by railroad regulation and concern rates, issuance of securities, liability to shippers and passengers and industrial relations. The questions of national authority which these raise tend to become questions of the statutory powers of the Interstate Commerce Commission (*q.v.*).

Flexible as are the bounds of federal and state authority, the newer forms of interstate enterprise transcend the simplicity of the traditional categories of governmental control. The intricate corporate arrangements in the public utility field raise particularly acute problems. The divorce of ownership from operation puts questions not dreamed of in the constitutional philosophy of John Marshall; whether, for example, rates charged to the consumer by an operating company can be regulated effectively without control over the managerial and financial activities of the holding company and if not, what mechanism of control should be adopted. Direct grip by law, state or federal, over holding companies appears inevitable. Indirect control by the states through scrutiny of the intercorporate relations of the local operating units is an alternative which has received impetus through recent Supreme Court approval [*Smith v. Illinois Bell Tel. Co.*, 282 U. S. 133 (1930)]. But technological changes even more basic than financial have begotten new situations for which old instruments of government will no longer suffice. The precedents in the law books are very tenuous aids for the solution of problems which the radio, motor carriers and electric power present to legal statesmanship. And to

look for a single solvent is to seek the philosopher's stone. In the electric power industry, for example, if the processes of law and legal administration are to be effective they must heed the economic interaction of the factors of generation, transmission and distribution, the economic interplay between local and interstate transmission, the relative volumes of intrastate and interstate transmission and the regional or national character of the interstate transmission itself. These and conundrums like them are now being explored by the Federal Trade Commission and will for many years continue to tax all the resources of wisdom of the Federal Power Commission (Federal Power Commission, *Eleventh Annual Report*, 1931). There is a growing realization that these issues cannot be settled in terms of explicit duality of state and nation. That simple dichotomy may be ill adapted to deal with regional forces ministering to regional prejudices. A variety of legal devices has been proposed to take account of these significances. On the administrative side it has been suggested that state boards act jointly as regional commissions or that a federal commission be supplemented by regional boards locally or federally appointed. On the legislative side the constitution offers the device of interstate compacts entered into with the consent of Congress. Legal inventiveness is not restricted to a few fixed legal categories when called upon to subdue the protean forms of interstate commerce to the diverse interests of society which they supposedly serve.

The power of Congress is a limitation not only upon state powers of regulation but upon those of taxation as well. Apart from the commerce clause a tax may be imposed only upon that portion of an enterprise which can fairly be attributed to the taxing state; various apportionment formulae have been attempted to meet the more general problem of double taxation (*q.v.*). To this territorial limitation the commerce clause adds restrictions where the activities in the state are part of a concatenation transcending the state line. The historic purpose of the commerce clause might have confined this limitation to taxes which discriminated against or "unduly burdened" interstate commerce. Thus the commerce clause prevents the imposition of a higher tax on goods coming from without the state than upon similar goods of local origin. Under the influence, however, of Marshall's dictum that the power to tax is the power to destroy—it awaited Justice Holmes a hundred years later to dispose of it: "The power to tax is not the

power to destroy while this Court sits"—the Supreme Court early declared that the ban extended to any tax, however general its incidence, in so far as it was a tax on interstate commerce. If consistently applied this doctrine would have resulted in pervasive discrimination in favor of interstate commerce at the expense of competing local enterprise. New Jersey, for example, would be forced to confer exemption on merchants who supplied New Jersey buyers with goods from New York warehouses in competition with merchants selling New Jersey goods. Even where the perversities of the doctrine are not so flagrant, it would have deprived the states of an important source of revenue from enterprises which burdened the state and received its benefits. Happily the states were not reduced to so unfortunate a predicament. The prohibition against taxes "on" interstate commerce contained a liberating equivocation. Indeed so effectively was the legal rather than the economic connotation seized upon that for a time the protection of interstate commerce from hampering state taxation threatened to become only a pious profession. The states were allowed to lay a tax on a concededly valid subject—property located or privileges exercised within the state—even though the tax was measured by elements, such as gross receipts from interstate commerce, that would not have been tolerated as subjects of taxation. The legislative legerdemain promoted by this distinction reached its climax in 1908 in a temerarious effort by Texas to distinguish between an invalid tax of 1 percent on the gross receipts of railroad companies and a tax on railroad companies "equal to" 1 percent of their gross receipts. The court shrank from carrying its formal doctrine to the ruthless logic of formalism. The first limits upon an old doctrine are apt to mark the beginning of a long retreat: in an opinion which presaged a new approach to the problem Justice Holmes warned that "neither the state courts nor the legislatures, by giving the tax a particular name or by the use of some form of words, can take away our duty to consider its nature and effect" [*Galveston, H. & S. A. Ry. v. Texas*, 210 U. S. 217, 227 (1908)].

The Supreme Court has not found the duty an easy one. If the adjustment of the claims of state and taxpayer cannot be made by any general formula, neither can it be left to unbridled empiricism on the basis of the amount and burden of the tax in each case. The state must have in advance some reasonable assurance of the permissible incidence of the tax. Moreover to

invoke standards of reasonableness with reference to an individual taxpayer presents a logical solecism; and practically a large tax on an interstate business may be less burdensome, where a similar tax is borne by businesses generally, than a small tax the impact of which is particularly upon interstate commerce. This will explain why although a carrier engaged in both interstate and intrastate commerce may successfully resist a tax levied in part on gross receipts from interstate commerce, it may be required to pay the same amount of taxes under a statute increasing the general tax rate but confined in application to gross receipts from intrastate commerce. The distinction between the taxation of a subject and the use of that subject as a measure of taxation has a real economic significance, in that the subject will indicate in the light of experience and analysis whether the tax will fall disproportionately upon interstate commerce. A broad subject is a reasonable guaranty that the incidence of the tax will be equitable. This has been recognized in decisions upholding a tax on property, even though the property is used in interstate commerce or valued by its connection with that commerce, and a gross receipts tax levied in lieu of a property tax. But in dealing with franchise taxes the court has given the subject of the tax a more formal importance. If applied to a corporation doing solely interstate business the tax has been held invalid, although if the corporation does both interstate and intrastate business the tax may be levied in respect of the latter. The court in sustaining a net income tax, even as applied to income from interstate commerce, based itself frankly on economic considerations; in contrast to the gross receipts tax the net income tax is imposed only if and to the extent that the commerce is profitable, and does not vary directly with the amount of the commerce. Particular importance attaches to the permissible scope of the net income tax in view of the increasing extent to which the states are adopting this form of revenue measure. In short, if the state frames its taxing system wisely, even interstate commerce can be made to pay its share for the support of the states wherein it operates.

An epitome of the whole process of legal adjustments under the commerce clause is presented by the original package doctrine. Although first announced in 1827 (*Brown v. Maryland*, 25 U. S. 419) as a prohibition of state taxation of foreign imports while they remained in their original packages and had not been re-

sold locally, the doctrine was in fact the enforcement of a policy which several states had voluntarily adopted and then abandoned. In *Brown v. Maryland* the tax was discriminatory and was laid upon importers; but the doctrine was uncritically carried over to cases of non-discriminatory treatment of goods from a sister state. In its uncongenial soil the doctrine suffered the fate of unfortunate transplantation. In 1923 it was finally uprooted [*Sonneborn Bros. v. Cureton*, 262 U. S. 506 (1923)]. The states may now levy property or sales taxes on all goods in the original packages except those imported from abroad. In its adopted field of state regulation, however, the original package doctrine evinced a more hardy vitality. After having been disregarded in relation to state prohibition laws it was later applied to them and it continues as a limitation on the exercise of state police power subject to the inroads that have already been noted. A corollary to the original package doctrine may be observed. Just as the state taxing power may lay hold of goods in the state of destination before the state regulatory power may be exercised, so there are indications that the taxing power may operate in advance of the regulatory power in the state of origin of the goods. Federal regulation, finally, may persist in the state of destination even after the original packages have been broken, as in the case of the pure food laws; and federal regulation may apply in the state of origin even before movement of the goods, as in the case of the antitrust laws.

The last fifty years have witnessed an efflorescence of federal authority having its roots in the commerce clause. In considering the extent to which the dominant forces of modern economic society have thereby come under federal control certain tendencies and limitations are suggested. The older forms of transportation and communication have been brought under broad national supervision. The Interstate Commerce Act of 1887, applicable in varying degrees to railroads and their water connections, express and sleeping car companies, pipe lines, telephone, telegraph and cable companies, marks the first step. Subsequent enactments have strengthened federal control and regulated the financial activities of the carriers. The Air Commerce Act of 1926 and the Radio Act of 1927 are recent additions to federal power. A second type of federal commercial legislation enacts prohibitions and penalties like those found in state police power enactments. In this group are the Lottery-Tickets Act of 1895, the Food and Drugs Act of

1906, the Mann Act of 1910, the Dyer Act (automobile larcenies) of 1919, the Packers' and Stockyards Act of 1921, the Grain Futures Act of 1922—this class of enactments, it is manifest, deal with activities closely related to the physical movement of persons or things. A third type of federal control takes its origin in the Sherman Anti-trust Act of 1890. These restrictions upon trade agreements of manufacturers and the tactics of organized labor involve perhaps the most permeating impingement of federal authority on business and industry. Yet even here the courts are guided in applying limitations on activities which are not themselves interstate commerce by a feeling for the "dramatic circumstances" of interstate movement, which in 1905 served to bring the so-called Beef Trust within the proscription of the Sherman Act. The extent to which such activities as corporate organization, finance (apart from national banks), insurance, stock exchanges, will yield to constitutional control by the central government, if the pressure of circumstances should make that desirable, may well depend, so far as lawyers' arguments go, on the extent to which they are dramatically linked to the element of distribution in the complex of commerce.

Pressures more powerful than even the most prescient language of constitution framers were bound to weld the loose congeries of the original states into a cohesive centralized nation. To a considerable degree therefore the Supreme Court registers inevitabilities in the political and economic unfolding of the United States. Yet even inevitable development may be eased or retarded by the constitutional channels through which the national life flows. The commerce clause undoubtedly has been utilized as the great centralizing vehicle in the American constitutional scheme. Barring the war power it is the deepest source of the affirmative exertion of national power. The national interest prevails, yet the states are not excluded from dealing with state phases of the nation's commerce. The states may to some extent regulate interstate commerce because they must—always with the power of Congress to gainsay through legislation and the power of the Supreme Court to annul through litigation. And so for a hundred years and more exertions of state authority within the field of interstate commerce have successfully passed the scrutiny of the Supreme Court. Practical necessities and shrewd judgments about practical matters decide the fate of state legislation when challenged by the power or the action of

Congress. State necessities, the fitness of state relief as against nation wide action, the limited manifestations of a given evil or the limited benefits of its correction, the actual interest of the whole country in a phenomenon especially virulent in a particular state, the advantages of local regulation balanced against the cost or inconvenience to interests outside the states—these and like questions are involved in the process by which the Supreme Court in concrete cases has held for or against state and national action in the interacting areas of state and national interests.

Ultimately these are phases of the central problem of the one and the many, which has been the leitmotif of American political and constitutional history. The solution of conflicts in the future as in the past will depend upon the prevailing philosophy of federalism of the Supreme Court justices, reflecting in turn views of American society which judges share with their fellow men. With the growing use of taxation as an instrument of state policy and the development of state schemes for controlled production the questions will become nicer and the adjustments more subtle. If the due process clause does not interdict these "social experiments in the insulated chambers afforded by the several states," the commerce clause remains to admonish that the insulation may have worn too thin. On behalf of the states it will be urged that demands for centralization, although in apparent harmony with the unifying forces of technology, frequently overlook possibilities of cooperative action; that there is a practical limit to effective administrative oversight and judicial control; that in matters not obviously of common national concern the states or at least regions of them have a localized knowledge of details, a concreteness of interest and varieties of social policy which themselves constitute values that it is to the highest interest of the nation to conserve.

FELIX FRANKFURTER
PAUL A. FREUND

OTHER FEDERAL STATES. The experience of the United States in adjusting the problems of the distribution of powers between the central government and the member states was widely known and carefully studied by many of the individuals responsible for subsequent federal constitutions, but the guidance offered by this experience was variously interpreted. Only Australia, Brazil and Argentina followed the lead

of the United States in confining to interstate commerce the power of the federal government over commerce. The Swiss constitution of 1874 (art. 31) merely guaranteed freedom of commerce and industry throughout the confederation, with certain exceptions including sanitary police measures and provisions relative to the practise of commercial and industrial pursuits. Other federations gave the central government control of all trade and commerce. The Reich under the constitution of 1871 had general control of commerce and trade where uniformity was essential but the administration and the details of legislation were the province of the *Länder*. Under the constitution of 1919 federal powers over both legislation and administration were increased. The Austrian constitution of 1920 gave powers both of legislation and of administration in respect to commerce and industry to the federal government, declared the federal territory a uniform economic zone and prohibited any hindrances on interstate or internal trade. Mexico in its constitution of 1917 gave the central government power to prevent restrictions on interstate commerce and to regulate for the entire republic in all matters relating to mining, commerce and institutions of credit (art. 73). In these countries the problem was essentially one of determining the limits between these broad powers over commerce and the powers specifically granted or impliedly reserved to the states.

The British North American Act of 1867 establishing the constitution for the Dominion of Canada also gave to the federal government exclusive control over commerce and trade (art. 91, sect. 2) as well as the power to legislate for the peace, order and good government of the dominion and to regulate the railways. The intention was quite evidently to profit by the difficulties of the United States by giving to the central government ample powers over commerce. In *Citizens Insurance Co. v. Parsons* [7 App. Cas. 96 (1881)], however, the Judicial Committee of the Privy Council found it necessary to restrict the literal meaning of the words "regulation of trade and commerce" in order to afford scope for the powers granted exclusively to the provincial legislatures in article 92, among them the powers to legislate on municipal institutions, property and civil rights and matters of a merely local or private nature and to raise provincial revenue by direct taxes and by shop, saloon, auctioneer and other licenses. The committee suggested that the clause might include

political arrangements in regard to trade which require the sanction of Parliament and also the regulation of trade in matters of interprovincial concern and perhaps the general regulation of trade affecting the whole dominion. It could not, it held, extend to the regulation by legislation of the contracts of a particular trade or business, such as fire insurance, in a single province. The court expressly abstained from defining the exact limits of the dominion power, leaving its determination to particular cases. In accordance with this policy of interpreting narrowly and strictly the nature of the powers granted to the dominion the Privy Council has upheld the right of various provinces to require licenses for the sale of liquor, to levy direct taxes on banks and insurance companies and to pass various measures of local police power which affect particular trades. By a process of judicial interpretation exactly the reverse of that adopted in the United States the Privy Council and the Supreme Court of Canada have reduced the power of the central government over trade and commerce to the point where, in view of the increased power over commerce gained by the United States Congress through judicial interpretation, the central powers over commerce in the two countries have become much more alike than seemed possible in 1867.

Next to the United States, Australia is the country in which the regulation of interstate commerce has presented the greatest legal and economic problems. The commerce clause (sect. 51, sub. 1) of the Australian constitution was framed in direct imitation of the American, giving the commonwealth power to make laws with respect to "trade and commerce with other countries and among the states." This section was clarified, extended and modified by certain other sections of the constitution. Federal control was definitely indicated as extending to navigation, shipping and state owned railways (sect. 98). Parliament was given the power to prohibit any undue, unreasonable or unjust preference or discrimination in railway rates as between one state and another (sect. 102). The states were forbidden to levy customs duties (sect. 90) or to impede interstate free trade (sect. 92), but they could levy inspection charges (sect. 112) and legislate with regard to intoxicants (sect. 113). The states were guaranteed against any action by the federal government favoring one state as against another (sect. 99) or abridging the rights either of states or of residents thereof to a reasonable use of the waters of

the rivers for conservation or irrigation (sect. 100). In a measure these detailed provisions represented an attempt to settle by constitutional provisions certain questions which in the United States had been settled by judicial decisions or by subsequent legislation. Of the latter nature was especially the provision (sect. 101) creating an Inter-State Commission "to be appointed by the Federal Parliament with such powers of adjudication and administration as Parliament deems necessary for the execution and maintenance within the Commonwealth of the provisions of this constitution with regard to trade and commerce and all the laws made thereunder." The commission never came to occupy its intended position in the governmental system; it became moribund after the Privy Council denied it the right to exercise the judicial powers granted it under the Inter-State Commission Act of 1912 [*New South Wales v. Commission*, (1915) 20 C. L. R. 54].

In interpreting the scope and meaning of the Australian commerce clause judges and constitutional lawyers have drawn heavily upon American experience. The question of what is commerce has been generally decided along lines following American precedents [*W. and A. McArthur Ltd. v. State of Queensland*, (1920) 28 C. L. R. 530]. The power over commerce granted to the federal government has been held not to apply to matters, such as conditions of employment, of which the effect upon trade and commerce is not "direct, substantial and proximate" [*Federated Amalgamated Government Ry. etc. Assn. v. New South Wales Ry. Traffic Employees' Assn.*, (1906) 4 C. L. R. 488]. The Australian Industries Preservation Act of 1906, intended like the Sherman Act to prevent monopoly and restraint of trade as well as unfair competition, has been held unconstitutional except in so far as it referred to trade or commerce with other countries or among the states [*Huddart Parker & Co., Pty., Ltd. v. Moorehead*, (1908) 8 C. L. R. 330]. The federal power over shipping and navigation has been held applicable only to oversea or interstate shipping, on the principle that the specific constitutional provision does not enlarge the territorial jurisdiction defined in section 51, subsection 1 [*Owners of SS. Kalibia v. Wilson*, (1910) 11 C. L. R. 689]. States have been denied the right to impose discriminatory burdens upon products of other states [*Fox v. Robbins*, (1908) 8 C. L. R. 115]. Until 1920 the doctrine of reserved powers—that the grant of power over interstate commerce

to the commonwealth reserved all regulation of intrastate trade to the states—had been applied in a number of cases to invalidate commonwealth acts. In that year in the *Engineers' Case* (28 C. L. R. 129) the High Court repudiated the doctrine and conceded to the commonwealth the right to regulate intrastate trade if that regulation was essentially involved in the exercise of any federal power. Despite this concession the feeling is strong in Australia that the powers of the commonwealth over commerce are inadequate. Three attempts to transfer to the commonwealth all power over commerce succeeded to the extent of passing both houses of Parliament but failed to secure the necessary vote in the popular referenda.

Argentina (art. 67, sect. 12) and Brazil (art. 34, sect. 5) also copied very closely the commerce clause of the United States constitution. The former by implication also adopted established American jurisprudence on the clause except in so far as peculiar conditions necessitated changes [*in re Lino de la Torre*, (1877) 19 S. C. N. 231]. In both Argentina and Brazil, however, the power of the central government was tremendously increased by certain general grants of power which have rendered more or less academic the question of the exact limits of federal power under the commerce clause. Thus the Argentine constitution (art. 67, sect. 16) gives the Congress power to provide for "all that conduces to the prosperity of the country, to the advancement and welfare of all the provinces"—powers so broad as to give the Congress complete control over the industrial development of the country. Similarly among the concurrent powers of the Brazilian Congress is the power "to encourage in the nation the development of letters, arts and sciences, as well as immigration, agriculture, industry and commerce without privileges that might hinder the action of the local governments" (art. 35, sect. 2). Interstate commercial relations in Brazil are complicated by the right of the individual states to levy export duties (art. 9, sect. 1) and under certain conditions import duties (art. 9, sect. 3). In 1896 the court declared export duties levied on products going to other states unconstitutional but reversed its position the following year in accordance with legislation passed by Congress. Two subsequent reversals by the court have left such export duties constitutional. Since the constitution specifically gives to the central government the right to levy import duties only on foreign goods, the states claimed the right to levy import

duties on goods from other states but the Supreme Court has repeatedly held such levies unconstitutional. The extent of state powers with respect to the levy of import duties was finally clarified and regulated by federal law in 1904.

The trend toward centralization of control over commerce in the federal state would seem to be clear from the foregoing analysis of the types of arrangements for the regulation of commerce prevailing in the various federal states. Succeeding federations have shown in their constitutions a tendency to accord to the central government more power over commerce than the fathers of the United States constitution were willing to grant in 1787. That grant itself has been tremendously expanded by the Supreme Court in response essentially to the demands of an expanding technique and scale of commercial relations. It is significant that in Australia which followed most closely the original scheme of apportionment set out in the United States constitution the dissatisfaction with this provision in particular and with federalism in general is very strong. Canada alone seems not to conform to this general centralizing trend in control over commerce, but Canada's experience must be interpreted in the light of the constitution's relatively liberal grant of power to the central government. Increasing economic integration within the various federal states has resulted in such increasing central control that the problem of interstate commercial relations has everywhere, except perhaps in the United States and possibly in Australia, become far less important than that of surmounting or somehow eliminating the barriers to international trade.

INTERSTATE COMMERCE COMMISSION. This federal administrative tribunal is unquestionably the leading governmental agency of economic control in the United States. Through its sweeping authority over the transportation of persons and property, especially by rail, it not only imposes extensive restrictions upon freedom of enterprise but exerts a dominant measure of positive control over both individual transportation agencies and the transportation system as a whole. In the exercise of this authority moreover there is a marked departure from traditional legal processes. Although the commission is a federal tribunal its most significant powers extend in practise to intrastate as well as interstate commerce; although it is an

administrative agency it continually adjusts controversies and prescribes courses of future action; despite the exercise of these judicial and legislative functions it institutes criminal proceedings and penalty suits, and it moves on its own initiative as well as in response to complaints and applications. Its regulatory activity in execution of vast grants of discretionary authority results in a series of governmental acts which, while subject to modification by the administrative tribunal itself, constitute for the most part conclusive determinations. The commission's performance on this basis is exerting an increasingly potent influence upon the status of the railroads and of the other carriers subject to its jurisdiction; and its administrative experience is providing a rich background for fashioning the character of other agencies of control, state as well as federal, particularly in the field of the so-called public service industries.

The commission's prevailing position, as influenced in large measure by the weight of its own informed recommendations, is the outcome of a course of development, legislative and judicial, extending over a period of more than four decades.

The original Act to Regulate Commerce, under which the commission was established in 1887, was a mere beginning. Because the states had been held to be without constitutional authority to regulate interstate railroad rates, even in the absence of congressional action, and in view of the growing predominance of interstate traffic, the federal government entered upon the tasks of control; because continuous supervision, impartial investigation and flexible adjustment of carrier-public relations were deemed to be imperative for effective control, resort was had to administrative regulation. The widespread prevalence of discriminatory adjustments was the most influential cause of the adoption of this federal legislation, just as the outcry against extortionate charges had lent primary impetus to the enactment of the earlier granger legislation by the states. The act of 1887 was designed principally to prevent unreasonable and discriminatory rates and practises; the provisions prohibiting pooling, requiring publicity of operations, dealing with accounts and reports and endowing the commission with investigatory power were calculated to facilitate the achievement of these main purposes. But serious difficulties progressively emerged which rendered this original legislation an inadequate basis for the commission's exercise of control.

Through reliance upon constitutional protection against self-incrimination unwilling witnesses withheld essential testimony from the commission; as a result of the procedure provided for the enforcement of administrative orders—whereby the commission was charged with the burden of securing compliance with its findings through judicial processes and these findings were to serve only as *prima facie* evidence of the facts—the adjustment of controversies was long delayed, and by considering proceedings *de novo* the courts tended to exercise a dominant influence in their disposition; because of restrictive judicial interpretations of some of the basic provisions of the act—those relied upon especially to prescribe future rates and to eliminate alleged long-and-short-haul violations—the commission found itself without adequate substantive power to mold on any positive basis the relationships which should subsist between the railroads and the public.

During much of the first two decades of the commission's existence therefore the need of bolstering up its position in various directions, both procedurally and substantively, was repeatedly brought to the attention of Congress. Part of the response manifested itself in the passage of the Compulsory Testimony Act of 1893 and the Expediting Act of 1903 for the more effective exercise of existing governmental authority; in the adoption of the Elkins Act of 1903, largely under pressure of the railroads themselves, for the prevention of departures from the published tariffs and the elimination of personal preferences; and as a parallel development, for the protection of persons and property, in the enactment of safety legislation. Not, however, until the passage of the Hepburn Act of 1906 under the vigorous leadership of President Roosevelt was the commission vested with reasonably adequate powers of regulation. By that legislation in recognition of the organic unity of the transportation function the jurisdiction of the commission was extended to a group of carriers other than railroads; the scope of railroad transportation subject to control was expanded to embrace auxiliary services and facilities, such as those provided by private car owners and industrial railroads and tap lines; the commission's authority over accounts and reports was strengthened by the sanction of penalties and by the right of access to and examination of the records of the carriers; above all, power was expressly conferred upon the commission to prescribe rates and practises for the future in lieu

of those found to be unreasonable or discriminatory, and the enforcement procedure was so changed that the commission's orders were made binding by their own terms with the support of heavy penalties, and the burden of testing their validity in the courts was shifted to the carriers. On this basis the commission came to exercise positive control over railroads and other carriers, and with the consequent narrowing of the scope of judicial review the method of administrative regulation came to dominate the field.

But administrative experience disclosed additional difficulties from time to time, necessitating further modification and expansion of the legislative structure. The first group of significant provisions was embodied in the Mann-Elkins Act of 1910. It rehabilitated the long-and-short-haul clause, so that relief from its prohibitions was made dependent upon the discretionary authority of the commission; it conferred power to suspend changes in rates, so that the commission might enter upon the regulatory process before the proposed rates became operative; it established a Commerce Court as a means of securing speedier, more uniform and more expert judicial determinations. Although the Commerce Court was abolished less than three years later, even this aspect of the 1910 legislation exerted a permanent influence upon the commission's status, since the most significant controversies during that short period concerned the lawful scope of judicial review and these controversies were almost uniformly resolved by the Supreme Court in support of the commission. Basically indeed the tendency of the Commerce Court to encroach upon the legitimate sphere of administrative power was responsible for the transfer of its jurisdiction to the district courts. The other important provisions of the Mann-Elkins Act not only resulted in a direct enhancement of the commission's authority but contributed to the enactment of further substantive legislation. While the new fourth section made possible far reaching curtailment of long-and-short-haul violations, particularly in southern and western territory, its application also emphasized the close interrelations between rail and water transport. Accordingly under the Panama Canal Act of 1912 provision was made for the dissociation of competing rail lines and water carriers, the commission to determine the existence or possibility of competition, and the commission's authority over joint rail and water carriage was extended in various directions. Similarly, while the rate suspension power was immediately uti-

lized in comprehensive proceedings as a means of preventing proposed advances in railroad charges, its application also emphasized the absence of reliable data of capital investment and property values. Accordingly under the Valuation Act of 1913 the commission was directed, although with little guidance as to controlling standards, to make valuations of the carriers' properties and to keep these valuations up to date—to initiate a vast research undertaking, which after almost two decades of investigation is not yet completed (*see* VALUATION).

But the commission's authority was to be still further developed in highly significant directions. In the decade after 1910 railroad facilities proved increasingly inadequate to meet growing transportation needs. Impaired railroad credit, which was widely recognized as the immediate cause of difficulty, was generally ascribed on the one hand to financial malpractices by important carriers and on the other to restrictive rate decisions by the commission. Both factors were doubtless operative in some measure, and they were alike grounded in the negative approach which had thus far characterized the development of the Act to Regulate Commerce. Restraint upon specific abuses, principally rate maladjustments, had been the chief objective of legislative policy; no affirmative responsibility had been imposed upon the commission so to utilize the regulatory process as to maintain and develop an adequate transportation system. This was evidenced by the lack of statutory guidance in the matter of fair return and by the absence of federal regulation of security issues; it was reflected too in the insistence upon maintenance of competition, in the statutory silence with regard to conflicts between state and federal authority, in the neglect of direct control over service and facilities. All these legislative defects contributed to the rapidly emerging transportation difficulties, which in turn were dramatically accentuated by the unprecedented traffic demands of the World War. Government operation of the railroad properties became inevitable during the period of this emergency, and the twenty-six months of federal control (January 1, 1918, to March 1, 1920) not only emphasized the fruitfulness of recognizing the unity of the national transportation system but afforded an opportunity for recasting the regulatory scheme in terms of such recognition. The roads were returned to their private owners under a system of regulation broadly reconstituted on an affirmative basis, in which the railroads of the country

were placed under "the fostering guardianship and control" of the commission.

The Transportation Act of 1920 involved many "new departures" from traditional legislative policy. In the field of rates and charges the commission's authority was expressly extended for the first time to matters of financial return, with emphasis upon the support of carrier credit and the maintenance of an adequate transportation system. This is evidenced by the statutory rule of rate making requiring under honest, efficient and economical management and reasonable expenditures for maintenance a fair return on the fair value of the railroad properties as a whole or in groups; by the recapture clause providing for the disposition and use of the earnings of individual carriers in excess of a fair return; by the requirement that joint rates be apportioned among participating carriers in furtherance of the public interest; by the express recognition of federal authority over intrastate rates found to be discriminatory against interstate commerce. With like ends in view the commission's directing powers were extended to the control of service practises, culminating in the extraordinary authority to order acquisition of facilities and extension of lines and under emergency conditions to direct the pooling of equipment, the common use of terminals, the establishment of priorities, the rerouting of traffic. Finally, an important group of enabling powers, to be exercised upon application of the carriers, extended the commission's dominant influence into the sphere of finance and management. New construction and abandonment of lines were made to depend upon its issuance of certificates of public convenience and necessity; the pooling of traffic or of revenue by competing railroads, the acquisition of control of one carrier by another through lease or stock ownership and the actual consolidation of railroad properties were made subject to its approval; the issuance of securities and the assumption of obligations were made dependent upon its authorization. While legislative policy on this basis was deemed to constitute a more intelligent and more constructive adjustment of relationships between the railroads and the public than had theretofore prevailed, the scope of the commission's powers was radically expanded thereby.

The sweep of the commission's control of economic adjustments appears not only in the wide range of substantive powers exercised over the railroads but in the variety of the types of carrier subject to its jurisdiction. While railroad

transportation was from the beginning and still remains the chief field of the commission's regulatory activity, the scope of its control now includes water lines under prescribed conditions as well as express companies, sleeping car companies, pipe lines employed in the transportation of oil or other commodities (except water and gas) and telephone, telegraph and cable companies. The actual assertion of authority over some of these carriers has been rather narrowly restricted; but there has been an increasing recognition of the intimate interrelationships, competitive and otherwise, which prevail between the various transportation agencies and of the need of still further extension of the commission's jurisdiction, particularly over water lines and motor carriers, if the primary tasks of railroad regulation are to be executed wisely and effectively and if necessary coordination in the transportation field as a whole is to be measurably achieved.

Although the commission's authority is expressly declared to be inapplicable to the transportation of passengers and property wholly within one state, its functioning jurisdiction embraces such control of intrastate commerce as is essential to the effective control of interstate commerce. This development is grounded, first, in the fact that identical instrumentalities simultaneously serve both types of commerce and, second, in the controlling circumstance that commercial enterprise does not accommodate itself to the artificial political lines which separate the states. Under these conditions the commission's regulatory activities normally comprehend many matters which are primarily of local concern. The prescribed accounting classifications and the required reports cover all traffic; the service regulations are applicable to the entire supply of facilities and the entire flow of commerce; the certificates of convenience and necessity generally embrace lines located or to be located wholly within one state and intrastate as well as interstate service; the issuance of securities by interstate carriers, even when the proceeds are to be used exclusively for intrastate facilities, is conditioned upon federal authorization and cannot be validated by state action; carrier combinations are generally dependent upon federal approval, and such approval exempts them from the restrictions of state law; state made rates which are found to be discriminatory against interstate commerce, whether because of the prejudicial effect of rate disparities upon specific persons and places or because of the

general financial burden imposed thereby upon the transportation system, are subject to the commission's direct control. Under the influence of congressional enactments, as interpreted by the courts, the powers of the states have become increasingly attenuated in this field.

But despite this centralization of authority the commission has tended to steer a statesmanlike course in dealing with state and federal relations: without subordinating dominant national interests it has largely avoided undue encroachment upon the legitimate sphere of local control. Only in the initial enforcement of the affirmative rate policy introduced by the 1920 legislation did it virtually occupy the entire field, with seemingly unnecessary disregard of the economic and governmental interests of the states. In due course by way of response to judicial dicta and to the lessons of more mature administrative experience a commendable spirit of restraint came to characterize its adjustment of jurisdictional issues. Only substantial disparities in charges which operate "as a real discrimination against, and obstruction to, interstate commerce" are now held to justify the assertion of federal authority; and even in such cases reliance is regularly placed upon the state commissions, in the first instance, for the removal of the maladjustments. A co-operative procedure following express statutory provisions has facilitated these developments. Due notice is given to the state authorities of all proceedings involving matters of intrastate concern, so that local representations may be made and cooperative action arranged; joint hearings and joint conferences are held in most such proceedings, so that on the basis of a common record and free discussion conflicting views may be harmonized and divergent results avoided; the facilities and services of the state commissions are frequently utilized by the federal agency as media of investigation and administration. While ultimate authority resides in the federal tribunal, this system of cooperation, voluntarily fashioned by agreement between the Interstate Commerce Commission and the National Association of Railroad and Utilities Commissioners, is achieving notable practical results—in removing maladjustments, in averting conflicts, in reducing to a minimum the necessity for direct federal action in matters primarily of state concern.

Perhaps the commission's outstanding characteristic as an agency of control lies in the vast scope of its administrative discretion. In the performance of its mixed functions it is not only

virtually unhampered by procedural restrictions but free to mold its substantive determinations in such directions and by such processes as in its informed judgment will best serve public ends. Despite the elaborate character of the legislation under which it operates, the guiding standards prescribed by Congress are usually so general that a continual stream of policy making administrative decisions is necessary to translate these general standards into concrete arrangements. The just and reasonable rates and practises which the commission seeks to maintain and develop are based upon the facts and circumstances of each proceeding, in the light of constantly changing conditions in both industry and transportation; and a like approach characterizes its disposition, in furtherance of the public interest, of the numerous and varied applications for approval of proposed courses of action in the newer field of finance and management. Although a body of controlling principles has been progressively developed in all phases of the commission's tasks, pragmatic considerations tend to dominate the course of administrative performance. Precedent often plays but a minor role; future needs are nicely balanced against the claims of vested interests and the pressure of established relations; typical data are frequently accepted as providing sufficient support for comprehensive findings; provisional orders are issued when calculated to achieve major public ends; experimental adjustments are encouraged; few obstacles are interposed to the rehearing of complaints and the reopening of proceedings; emphasis is directed to the achievement of flexibility of relations through continuity of control.

Furthermore this broad exercise of discretion is virtually free from external limitations imposed by the courts. Through a self-denying interpretation of basic statute the courts have sharply narrowed the scope of judicial review in recognition of the general intent of Congress to constitute the commission the dominant agency of control. In most matters involving alleged violations of the Interstate Commerce Act preliminary resort must be had to the commission in order that uniformity of results molded by expert judgment may be adequately safeguarded; denials by the commission of the relief sought are held to be beyond the reviewing powers of the courts, in order that the discretion of the courts may not be substituted for that of the commission; and upon the commission's assumption of primary jurisdiction and its issuance of affirmative orders the grounds of judicial cen-

sorship tend to be confined essentially to the single issue as to whether the exerted powers could be and were in fact vested in the commission. The commission's acts may be invalidated because they infringe upon constitutional limitations, because they exceed the scope of statutory authority, because as a result of want of evidence or mistake of law they involve arbitrary action or abuse of discretion. Even in these terms there is no extensive judicial interference with the commission's findings and orders. Despite the far reaching expansion of regulatory processes there has been an almost complete absence of proceedings in which either the underlying legislative provisions or the administrative decisions have been invalidated on constitutional grounds. There have been frequent disagreements between the commission and the courts in matters of statutory interpretation, but the gaps left by such judicial curtailment of administrative authority have generally been filled in due course by amendatory or supplementary legislation; and while censorship for mistakes of law broadly conceived has afforded numerous opportunities for judicial encroachment upon administrative judgment, it has almost invariably been restricted in the maturity of the commission's status to the maintenance of basic procedural safeguards and to the enforcement of legal principles of general applicability. The Supreme Court's approach in connection with the valuation controversy—notably in the famous *O'Fallon* case [*St. Louis and O'Fallon Railway Co. v. United States*, 279 U. S. 461 (1929)]—seems to constitute a striking exception to the general doctrine that the commission's determinations when supported by evidence and within the lawful scope of its delegated power are free from judicial interference; but even in this proceeding the adverse decision of the majority of the court was professedly based upon the commission's mistaken construction of the relevant statutory provisions, in the light of principles deemed to have been established in previous valuation cases with regard to the consideration to be given to current reproduction costs. It has been repeatedly affirmed that issues of fact, primary or ultimate, which necessarily involve the exercise of discretion, are subject to conclusive settlement by the primary tribunal. The courts do not pass upon the weight of the evidence, nor do they render independent judgment upon the wisdom or expediency of the policies and practices sought to be enforced. The commission is recognized as the tribunal "appointed by law" and "informed

by experience" to which the tasks of regulation have been committed, the courts merely providing negative safeguards against abuse of power.

The accumulation of regulatory tasks and the expansion of administrative responsibilities have resulted in important developments in organization and procedure. The commission's original membership of five has been increased through successive amendments to eleven, and the commission has been authorized to act through subdivisions of this membership, the decisions of which, subject to ultimate control by the entire body through rehearing, possess the same effect as those of the commission. The staff has grown from less than a dozen to about two thousand, and expenditures from somewhat less than \$100,000 during the first full year of the commission's existence to more than \$8,000,000 for 1930. There have been many reorganizations of the internal mechanism of administration; the bureaus of the commission, which not only perform routine tasks but participate intimately in the processes of regulation, now include those of formal cases, informal cases, traffic, valuation, finance, law, inquiry (prosecutions), service, safety, locomotive inspection, accounts and statistics. Originally the commissioners personally examined complaints, held hearings, conducted investigations, prepared reports, rendered decisions, issued orders. These duties are now largely performed, at least in the first instance, by attorney examiners and other subordinate employees; but by pursuing a liberal practice in permitting oral argument before divisions or the entire body and in authorizing the reopening of proceedings and the rehearing of complaints as well as through a carefully developed system of internal conference and cooperation the commission has encountered no insurmountable obstacles to fashioning harmonious policies, attaining reasonably uniform results, assuming informed responsibility for findings and orders. Nevertheless, the extent and diversity of the commission's tasks have given rise to serious problems of administrative pressure. The commission is probably the most overworked body in the entire governmental establishment, and it is becoming increasingly difficult to maintain its various activities on a measurably current basis. Procedural experiments involving the voluntary elimination or curtailment of formal hearings have tended to afford some relief; further improvement would doubtless result from increased appropriations, especially for additional examiners to handle

formal cases, and also perhaps from the delegation of authority under proper safeguards to individual commissioners and specified employees as recommended by the commission. But more drastic expedients—the establishment of independent or subordinate regional commissions, the creation of parallel regulatory tribunals in the sphere of finance broadly conceived, the organization of a cabinet department of transportation to exercise general administrative supervision over the railroad system—have been proposed from time to time. While the organic character of the regulatory process and the high quality of the commission's performance tend to cast doubt upon the wisdom or feasibility of most such proposals, the suggestions direct attention to practical aspects of the increasingly important issue of administrative effectiveness.

The commission is called upon to accommodate such numerous and far reaching conflicts of interest that its decisions frequently elicit criticism and disapproval, but it is a matter of general agreement that its functions are indispensable and the services which it renders highly salutary. Its vast powers are usually exercised with admirable restraint, and it accords dominant influence to the complex realities of the situations with which it deals. Without attempting to reconstitute the railroad industry on any uniform basis of abstract principle, the commission is none the less constantly safeguarding the interests of the public in a great variety of directions; and at the same time it is not unmindful of the legitimate claims of the railroad owners and is protecting the carriers themselves against the excesses of competitive practise and the mistakes of corporate self-seeking. With the increasingly extensive inroads upon railroad traffic by motor trucks, buses, water carriers and pipe lines it has become essential that the commission direct itself to the outstanding task of effecting a proper coordination of the various carrying agencies. The commission's recommendations for added statutory authority in this sphere will doubtless come to fruition in due course; and much may also be gained from its proposals for repeal of the recapture provisions and for modification of the rule of rate making as well as from progress under its supervision in the actual accomplishment of railroad consolidations. In face of these large responsibilities, however, it is of crucial importance that the commission's administrative independence be jealously maintained. Executive or legislative interference tends to substitute political power for informed and disinterested

judgment. In recent years such interference has not been altogether absent. On the executive side there has been some manipulation of the powers of appointment and confirmation under pressure of disgruntled litigants and in general furtherance of political ends; and on the legislative side there has emerged a tendency to resort to direct congressional action, as through the largely futile Hoch-Smith Resolution of 1925 for according relief to agriculture, in similar response to dissatisfaction with the commission's orderly determinations. Such developments have not hitherto involved serious consequences but they tend to undermine administrative responsibility, to distort the closely integrated system of regulation, to drag into the political arena complicated technical questions which can be settled properly only through patient inquiry and expert judgment. Freedom as well as power is essential to the satisfactory performance of the commission's important labors.

INTERSTATE COMPACTS. *See* COMPACTS, INTERSTATE.

INTERVENTION. Intervention, in international law, occurs where one state interferes by force or the threat of force in the affairs of another state. It may be directed, as was the case during the earlier history of the practise, against a recognized member of the family of nations or, as has happened on numerous occasions during the more recent period of planned colonial expansion, against an outlying state with a less advanced civilization (*see* PROTECTORATE).

As a technical term the word is of comparatively modern origin, but the idea comprised in it may be traced back to E. de Vattel, the Swiss jurist, whose *Droit des gens* was first published in 1758 (2 vols., Leyden). He laid down the general rule of state independence that every state has the right to govern itself as it thinks fit, adding the corollary that no foreign power has a right to interfere with a state apart from friendly help unless it is asked to do so or unless prompted by special reasons. Vattel's frequent repetition of this corollary was no idle tautology. The notion that states were independent was recognized in theory, but in the European practise of that age little attention was paid to it by the more powerful states when it did not suit their purpose. From the Peace of Utrecht in 1713 to the Treaty of Vienna in 1815 there were events which might justify serious speculation as to whether rules of common morality applied as between states. Even while Vattel wrote, Frederick II's plunder of Silesia in direct contravention of his father's guaranty must have been fresh in his memory. The very king in whose diplomatic service Vattel was employed, Augustus III of Saxony, had been forced as a ruler upon the Polish nation by the arms of Russia and Saxony.

The writers on international law who succeeded Vattel forged and welded the materials scattered throughout his book into a more compact form, but it was some time before "interference" was insulated as a substantive branch of international law and longer still before it acquired "intervention" as a technical name. This hardened as a distinctive term during a period extending roughly from 1817 to 1830. The

reason for its swift evolution during this period is paradoxical. The gross infractions of state independence were so numerous that jurists were forced to give the topic of intervention, whether justifiable or otherwise, an increasing amount of attention. Within the brief span of the twelve years between 1820 and 1832 the Holy Alliance exploited its principles of interference in Naples and Spain, Greece and Belgium became independent states by the intervention of foreign states and French and Austrian interventions balanced one another in Italy. English historians have been inclined to regard Castlereagh's circular dispatch of 1821 as the *locus classicus* on non-intervention; yet it was Castlereagh who dispatched a British fleet in 1814 to punish the Norwegians because they refused subjection to a Swedish king.

Even in current international law intervention has a perplexing vagueness of meaning, but three tolerably distinct varieties are noticeable. The commonest type, the type which has been discussed in the above historical sketch, is internal intervention, or interference by one state between disputant sections of the community in another state, the matter of dispute being usually but not invariably some constitutional change. Since state independence is the foundation of modern international law, non-intervention is now the rule and intervention the exception. It took some time to establish this fact, but for the last century it has been generally recognized as prevailing within the family of nations. Internal intervention when it occurs is directed against abnormal conditions resulting from internal strife, and as a general rule the expectant treatment of non-intervention has come to be preferred to the surgery of intervention.

A second type of intervention so-called consists in punitive measures adopted by one state against another to enforce the observance of treaty engagements or the redress of illegal wrongs. Such interventions occurred with considerable frequency throughout the nineteenth century, as, for example, the blockade by France in 1838 of the coast of Argentina on the ground of the alleged ill treatment of French subjects by the local government; the warlike expedition sent jointly by England, France and Spain in 1861 to compel Mexico to make compensation for injuries inflicted upon resident foreigners in Mexico and upon their property; the English embargo on Greek shipping in 1850 as a means of redressing the wrongs suffered by Don Pacifico and other British subjects; the naval expeditions

dispatched against Korea in 1866 by France and the United States to punish in the one case the murder of a French apostolic vicar and in the other the destruction of an American vessel and the massacre of its crew. The plea of protection of nationals and national property in backward areas as well as the collection of debts has often been advanced, especially in more recent times, as justification for forceful interference by an imperialistic power, notably by the United States in the Caribbean and Central American areas. All such proceedings are essentially measures of redress falling short of war and might more properly be referred to that branch of international law under some such subhead as reprisals, embargo or pacific blockade. They would not have been styled interventions but for the capricious application of that term; and confusion ensues from singling out certain pacific blockades as interventions. It is possible for punitive intervention to be closely followed by internal intervention, as happened in the proceedings instituted by England, France and Spain in 1861 to secure redress for injuries inflicted by Mexico; in spite of the protest and withdrawal of the other two powers France proceeded beyond the original aim and attempted to coerce Mexico in its choice of internal governments.

A third type of intervention, usually referred to as external intervention, consists in interference by one state in the relations—usually the hostile relations—of other states without the consent of the latter. The great majority of such interventions have had as their aim the promotion or settlement of a war between the states interfered with. It might be said that until quite recently the cardinal difference between internal and external intervention lies in the fact that while the causes which justify the former are within the province of international law, those which lead to the latter are outside its scope, however appropriate their discussion may be to the sphere of morals. For external intervention usually involves participation by the intervener in a war, and modern international law does not profess to classify the causes of war as just or unjust. But since the institution of the League of Nations in 1919 this doctrine has been seriously modified. Article 11 of the Covenant of the League declares that any war or threat of war, whether immediately affecting any members of the League or not, is a matter of concern to the whole League, which shall take any action that may be deemed wise and effectual to safeguard

the peace of nations; and not only are elaborate provisions made in other articles for the settlement of disputes between member states but certain topics are expressly specified as generally suitable for arbitration. It is true that the Covenant, like other treaties, is binding only on those states which have acceded to it, but these are so numerous and powerful that it is difficult to say that the causes of war are still a matter of indifference to international law. Consequently every war, whether it originates as an external intervention or not, must since 1919 be regarded as a matter of interest to international law, although there is as yet no genuine prospect of a reversion to the attempts of eighteenth century jurists to catalogue the causes of war as just or unjust.

Since all three forms of intervention involve force or the threat of force, the question is raised as to the difference between intervention and war. This is found to lie not in the acts of the parties but in the intention of one of them. The intervening state in spite of the hostile character of its conduct and of its recognition as such by the state affected usually regards pacific relations as uninterrupted. The touchstone is to be found in the circumstances which immediately precede the attack. The claim of the intervener may be reluctantly acquiesced in, in which case the intervention is non-belligerent; or it may be taken up as the gage of war, and then it becomes belligerent. When it reaches that stage the rules governing the contest differ in no respect from those applicable to any other war, except in those instances of internal intervention which take the form of assisting a mother country to subdue rebels to whom recognition of belligerency has not been accorded.

Discussion as to the theoretical justification for intervention may most profitably be limited to internal intervention, since from the very nature of the other two types exhaustive classification of their grounds is impossible. At one time or another some forty justifications of internal intervention have been advanced, most of which were of the flimsiest description and mere excuses for violent interference by one state in the internal quarrels of another. Out of this number only three are regarded by modern international law as unimpeachable.

"If," writes Hall in the classic statement of the first of these justifications, self-preservation, "a government is too weak to prevent actual attacks upon a neighbour by its subjects, if it foments revolution abroad, or if it threatens hostilities which may be averted by its overthrow, a

menaced state may adopt such measures as are necessary to obtain substantial guarantees for its own security" (*A Treatise on International Law*, 8th ed. by A. P. Higgins, Oxford 1924, p. 339).

Or again intervention is clearly justified as a means of checking unlawful intervention by another state. Such, for example, was the help afforded by Great Britain to Portugal in 1826 in order to secure the Portuguese throne against the attacks of Portuguese subjects stimulated by Spain.

In the third case, where intervention is justified on the grounds of an existing treaty right, a distinction must be drawn. If one of the parties to a struggle which is in actual existence concludes a treaty with a state authorizing its interference and in effect making it an ally, the interference is unlawful in spite of the treaty. Such treaties were common enough in time past; but now the rule of state independence has hardened sufficiently to make them unlawful, since in general a state must settle for itself its own form of government, a right which cannot be alienated by a single disputant section. Where, however, such a treaty has been concluded between two states before any dispute has arisen in one of them, it is impossible to say that it is unlawful. It may turn out to be unwise when occasion arises to put the treaty into operation, but a state is permitted to alienate to another state even its entire sovereign powers. For example, the Treaty of Havana in 1903 and the Treaty of Washington in the same year gave the United States lawful rights of intervention in Cuba and Panama respectively. Another example of such intervention is that provided for by the Treaty of Versailles, according to which the League of Nations may under certain conditions intervene to secure equitable treatment of racial, linguistic and religious minorities.

Beyond these three accepted grounds of justification there are others as to which international practise is uncertain. The most conspicuous of these are humanitarian intervention and collective intervention. The former has been repeatedly put forward to support interference designed to terminate civil discords accompanied by brutalities revolting to the notions of western civilization; such were those repeatedly undertaken by the European powers in Turkey during the nineteenth century. As to the second the only plea in its favor is that it usually excites less disapproval than intervention by one state because it is less likely to be selfish. But it is impossible to dogmatize as to the legality of either, because

most interventions of this or indeed any other kind have been based on a variety of motives, some just, some doubtful, some unjust. It is this fact which makes it so difficult to deal with the grounds of intervention in a generalized fashion instead of taking each case on its own merits. Thus neither nationality nor religion can be now regarded by itself as an adequate reason for intervention, but it has often happened that an intervention on either of these grounds has been confused by a plea based upon several others at the same time.

The social and political consequences of intervention in its varied forms and disguises do not lend themselves to brief summary. During the eighteenth and nineteenth centuries it repeatedly stifled democratic aspirations in the minor European states, as in Italy before its unification, and postponed freedom at the cost of continued oppression. Occasionally it produced beneficial results, as in the intervention which led to the creation of the modern kingdom of Greece in 1830. The recognized pretexts for intervention seemed even more convincing in the eyes of the family of nations when invoked against remote states addicted to civil discord in one form or another and so obviously lacking in the essentials of nineteenth century political and economic stability.

Intervention has been and probably still is inevitable as one means of standardizing the civilization upon which international law is now based. From the point of view of maintaining peace there is something to be said for the suppression of internal discords in another state when it is common knowledge that no revolution can break out in a European state without the likelihood of the balance of power between other states being upset. In many instances this is at best an excuse and not a justification, but it does show clearly that a policy of isolation, if it signifies absolute indifference to what occurs in other states, is at present neither advisable nor practicable. If any change in the trend of ideas about intervention is perceptible it is this. In the future intervention is more likely to be undertaken collectively, and the threat in it will more probably be one of economic outlawry—which is one of the sanctions of the Covenant of the League of Nations—rather than one of actual war.

INTESTACY. See INHERITANCE; SUCCESSION, LAWS OF.

INTIMIDATION as a means of achieving desired ends is a feature of behavior where power or authority is based primarily and essentially on force. The less the public feels bound by standardized ethical norms of conduct, the larger are the opportunities of using intimidation. It calls for a technique calculated to evoke fear in the party which is expected to do or not to do certain things, without, however, resorting to direct violence, which would bring the intimidator into conflict with established authority and law. Intimidation is presumed to border on violence,

carefully enough not to cross the line which demarcates the former from the latter yet closely enough to leave no doubt in the mind of the party of the second part that the party of the first part means business.

The distinction between intimidation and violence, on the one hand, and intimidation and persuasion, on the other, is so subtle and elusive that, for example in the field of industrial relations, where intimidation is a part of the workaday procedure, the American courts have found it next to impossible to lay down definite formulations and differentiations between the permissible and the impermissible. While most courts repeatedly have declared peaceful picketing entirely legal provided the picketers abstain from "unlawful intimidation," thus assuming lawful intimidation as a possibility, the Appellate Court in Chicago in 1921 in two separate cases declared emphatically: "There is no such thing as peaceful picketing" (221 Ill. App. 299, 303). "The very fact of establishing a picket line by the appellants is evidence of their intention to annoy, embarrass, and intimidate the employees of the appellee company, whether they resorted to physical violence or not (221 Ill. App. 322, 336). The United States Supreme Court in a decision handed down by Chief Justice Taft in 1921 postulated the right of picketing workers to attempt peaceful communication for the purpose of persuasion but also declared that "if . . . the offer is declined, as it may rightfully be, then persistence, importunity, following and dogging become unjustifiable annoyance and obstruction which is likely soon to savor of intimidation."

Intimidation as a practise is not limited to parties in the opposition who do not share in the privilege of operating, controlling or directly influencing the machinery of government and the administration of law. The resort to intimidation is also practised by persons, groups and institutions of functioning authority as an extralegal means of achieving desired political, economic, fiscal or other pecuniary ends.

Employers seek to intimidate employees by holding out the threat of discharge in order to prevent them from joining trade unions. Enforcement of the so-called yellow dog contracts is one of the means to that end. Potential union organizers among the employees are made to feel that they are risking their jobs by "butting in" on what is "none of their business"; the "agitators" are spied upon and may be directly discharged to instil fear in the hearts of the men at work. Where the employees live in what is

known as a company town, intimidation is achieved by warnings that disloyalty to the employers will result in the cutting off of credits in company stores or in eviction from company owned homes.

Where trade unions are firmly established, employers may seek to intimidate their employees by the prosecution of conspicuous union organizers. The celebrated case of Tom Mooney originated in an attempt of the San Francisco utility companies to intimidate all organized labor in the city. The companies may sometimes have the tacit acquiescence of the standpat element of the trade union movement in a fight on a radical leader, if the conservatives consider their own position endangered or threatened by the ascendancy to power of the radical element. Or employers may seek to intimidate the unions in order to force them to yield important concessions, to which end they will seek to arouse public sentiment against organized labor as responsible for the high cost of living or for the falling off of foreign trade.

Workers on strike seek to intimidate other workers who wish to take their places in the establishment involved. Intimidation need not necessarily be practised in the vicinity of the workshops. The strikers may attempt to reach their competitors at their homes or on some adjacent thoroughfare. The technique of intimidation varies from massed demonstrations before the workshop, accompanied by loud expressions of opprobrium, to the use of subtle yet persuasive methods of conveying the strikers' views of the situation to those who are consciously or otherwise engaged in breaking the strike. Where professional strike breakers are called in, the strikers seek to frighten and discourage them and to force their withdrawal from the scene. For workers who are engaged in strike breaking activity because they need the jobs for their living a different technique is used; the methods are those of persuasion, of demonstration and of appeal to the obligations of solidarity and brotherhood. This sort of approach often proves effective, especially in countries where labor is traditionally and socially class conscious and presents a largely homogeneous racial entity. In the United States, however, where differences of economic position have not generally evolved into social class divisions, where labor solidarity is tempered more often than not by job consciousness and where race and language lines cross those of economic class, it would seem that methods might tend toward intimidation

and violent expression of disapproval rather than toward peaceable communication and persuasion. But this is only rarely the case, judging by the conclusions arrived at by the United States Commission on Industrial Relations, which held that "the greatest disorders and most acute outbreaks of violence in connection with industrial disputes arise from the violation of what are considered to be fundamental rights, and from the perversion or subversion of Governmental institutions."

The workers in most cases do not view their recourse to intimidation in an industrial dispute as contrary to law. Conservative or radical, workers look upon their right to their jobs as a basic and indisputable condition of their welfare. On the other hand, the organs of public authority in objecting to intimidation of strike breakers assume the abstract individual right of any worker to work whenever, wherever and under whatever conditions he chooses; this was the view of Charles W. Eliot when he declared the strike breaker "a national hero."

Intimidation is used in the struggle of labor factions for supremacy. The labor group organized into one trade union may act as a monolithic collective whole when it faces an attacking outside power but it is very often much divided within. Contests for leadership, while they may be couched in statements of differing opinions on policy and tactics, are more often presented in such a way as to carry a threat to the rank and file that might be misled into following the opposition. The advantages of a material nature dependent upon maintenance of the leadership in power are featured prominently. The opposition to be silenced by intimidation need not be a minority. A majority may be kept in dread of the danger to which the well being of the members will be exposed, should a change of administration take place. The intimidation technique begins with publicity which plays up the governing machine, presenting it as endowed with extraordinary talent and diplomatic skill, as doubly powerful because it is admired by the overwhelming majority of the rank and file and respected and feared by the employers. Another part of the intimidation technique is running down the opposition as inimical to the best interest of the union. The exclusion of the leaders of the opposition from initiating any constructive action which may win for them the confidence of the rank and file is also a part of that technique. The membership is constantly confirmed in the thought that the opposition

leaders are phrasemongers, good for nothing faultfinders; and the contenders for office and power themselves are made to feel that they stand no chance of ever functioning in any capacity within the organization unless they are ready to accept terms imposed by the administration. The more drastic procedure in the intimidation technique is that of depriving opposition leaders of their membership in the union and thereby excluding them from jobs in the industry.

The intimidation of radical minorities in trade unions presents for the most part no aspects distinctive from the practises of intimidation where an ordinary contest for power takes place. The technique is generically similar to that used where power is in the hands of the radicals themselves, who excommunicate dissenters or objectors to their policies. The historic case of Sacco and Vanzetti is illustrative of what a social group in power will do to intimidate radical dissenters, a game of intimidation practised on a state wide scale. The treatment accorded by the Communist parties everywhere to the followers of Leon Trotsky after his banishment from the Soviet Union may serve as an illustration of the other aspect of this situation. The elimination of Trotsky from the country whose revolution he had helped crown with success and to which he never forfeited loyalty was justified by the claims that his presence in Russia would constitute a danger to the Soviets. In the other countries "Trotskyites" were excluded as a means of intimidating dissenters.

The intimidation of voters by employers interested in certain kinds of politics is a relatively simple procedure. The voters are intimidated by fear of material disadvantage as well as by the odium of nonconformity. Following the Civil War Republican campaign managers practised what the Democrats called "waving the bloody shirt." The campaign for McKinley in 1896, with finance and industry seriously alarmed over the "free silver" danger, was notorious for the variety of means used to intimidate voters, especially the workers, to whom William Jennings Bryan was making a strong appeal. Employees were discharged for turning out to see or hear Bryan; employers threatened to "close down" their factories should McKinley be defeated. Business contracts were made out to contain an invalidating clause in the event of Bryan's election. The Republican party's self-assumed custodianship of prosperity has intimidated and stampeded voters on many occasions since 1896

by the implied or open threat of hard times should the opposition party win.

There are other forms of political intimidation. The political machines which usually dominate local politics practise intimidation on a large scale. Opposition voters are intimidated in various ways, some of them subtle, others crude, in order to keep them away from the polls. Business men are made to fear that contracts or favors may go to competitors if they do not "stand in" with the machine. Criticism of the leaders within the machine is usually fatal for the aspiring politician. The power to grant or withhold patronage is a strong weapon of intimidation in both local and national politics. And intimidation of course is an indispensable weapon in suppressing opposition and maintaining unity in war time.

A whole social group may practise intimidation upon another group, as is the case in the south, where the intimidation of the Negro assumes many forms in which are intermingled factors of a racial, economic, political and social nature. In Europe national minorities are intimidated in much the same manner. In countries where aliens are numerous they are the victims of many forms of intimidation, one of which is the threat of deportation hanging over alien radicals.

Intimidation is also a part of the technique of business. Competitors resort to intimidation which may merge into violence. The oil industry of the earlier years presents many examples of the resort to violent intimidation. Lowering prices in order to force competitors out of business may be considered a form of intimidation. Price associations and cartels often resort to intimidation to force recalcitrants into line. Chain stores by threatening to withdraw their orders sometimes force onerous terms upon small manufacturers who have come to depend upon the chain as their main market. Distributors of securities may be forced to handle certain objectionable issues by the investment banker's open or covert threat of ceasing further transactions. And financial groups out to secure control of particular corporations or to achieve other ends may make use of various forms of intimidation which flow from the possession of great power.

Intimidation is the stock in trade of gangsters and minor racketeers in the United States. They intimidate the small business man and sell him "protection" against the danger of which they make him aware. The small business man or

service agency is continually harassed, annoyed and intimidated by sub rosa representatives of the racketeering gang, while a formal representative offers in matter of fact business fashion protection from the harassing, annoying, intimidating crew. In recent years this industry has muscled its way into the labor union field. The gangster comes to the union, for instance, when it is engaged in a conflict with an employer, and offers to intimidate the adversary and force him to terms. Although his charges for this service are usually reasonable, he later sees to it that union officers become implicated in an overt act, after which he has the union in his grip and can collect as much as the traffic will bear. Should the union try to dispense with the gangster's services, he may intimidate it into retaining them. Having established connections within the union he next approaches the employer, to whom he sells protection from the union's organizing efforts. To convince an employer who shows little anxiety to be protected the racketeer, acting through his gangsters stationed in the union, will engineer "trouble" in order to prove that it pays to be protected. A large scale employer may not fall prey to the game of intimidation; nor will a well organized and intelligently led union open its doors to gangsters.

The success of the practitioners of intimidation is largely due to the growing insecurity of large masses of workers and to the narrowing of opportunities hitherto open to the intermediate social groups above the working class and below the business and professional classes. The peculiarities of the American system of law administration and enforcement, the conflicting jurisdictions of city, state and federal administrative and judicial authorities, furnish an appropriate setting for traffic in intimidation. The absence of normalized socio-ethical concepts and the all pervading reverence of material success as intrinsically valuable, characteristic of a population still in a condition of flux, supplies a milieu in which intimidation not only flourishes but is accepted as a legitimate part of the routine of living. The social process is consequently demoralized and aberrated, as the practise of intimidation makes more severe and still more complicated the conflicts unavoidable in a complex social system based on a pecuniary civilization.

INTOLERANCE. People are apt to condemn or deplore intolerance in others and condone or honor it in themselves. Perhaps it would be more just to say that it appears to them bad in some cases and good in other cases: bad when it is intolerance of the good and good when it is intolerance of the bad. Intolerance in the abstract has lost caste, but abstract intolerance happens to be of no social significance. And it is generally agreed that in the concrete a point is invariably reached beyond which tolerance ceases to be a virtue. In other words, contemporary conditions of life enforce a practical kind of toleration and leave the intolerant spirit largely untouched.

In analyzing the concept of intolerance a distinction must be drawn between the act of tolerating and the tolerant disposition; between the unwillingness to tolerate and the intolerant frame of mind which may or may not be associated therewith. According to the general assumption the person who tolerates a thing is in so far tolerant and the person who does not is to that extent intolerant. Intolerance is held to be an inevitable corollary of deep conviction, especially in social and political spheres, where vigorous discrimination is the beginning of practical wisdom.

This familiar viewpoint is open to serious qualification. Intolerance is far removed from discrimination in the sense of unwillingness to condone certain beliefs or practises. It will hardly be contended, to take an obvious example, that refusal to risk the effects of contagion by disease or insistence upon the isolation of the sick is evidence of intolerance in any proper sense of that word. In a variety of other situations as well discrimination may result from an open minded examination of the factors involved and from a perfectly rational apprehension of the unhappy results entailed; while, on the other hand, so-called tolerance in its negative aspect of acquiescence may be due to nothing more than ignorance or indifference. It becomes increasingly clear that intolerance turns less on the attitude of yes or no than on the nature of the feelings and the state of mind which lie back of the particular attitude. Intolerance does of course in the same way as discrimination deny

sufferance to the object of disapproval. But this is merely its outward aspect. The deep lying source of this outer attitude is a repudiation of the whole technique of empirical experimentation to which human beings acting as individuals or groups owe such objectivity of judgment as they are capable of. Another inner characteristic of intolerance is its cold indifference to the larger social implications of the situation at hand and its resultant tendency to minimize or deliberately to ignore broader relationships which if properly appraised would constitute the determining factors in the formulation of an attitude or policy in regard to the particular problem. This imperviousness to social and humanitarian considerations, combined with the refusal to appraise social programs in a tentative, experimental manner and in this way to keep these programs actively responsive to growing experience, may therefore be abstracted as the essentially distinctive qualities of the intolerant attitude.

The primary source of intolerance as an active social disposition is dedication to a fixed goal. Such dedication may vary from a more or less blind "drive" to a thoroughly conscious yet frenzied espousal or to a calm, reasoned commitment. The values which intolerance aims to preserve may be accreted by accident or circumstance to a general economic or political purpose, as in Fascist Italy. In such cases in proportion as these drives remain actively dominant the values are capable of an opportunistic evolution up to the point where they become too closely merged with the broader purpose to admit flexibility. The values may, on the other hand, constitute an integral component of the original propulsive purpose, as in Communist Russia; here the margin of compromise is correspondingly diminished. The religious institution and the state are the chief types of organized groups in possession of the authority and the sanctions to enforce their conception of values. The ground of intolerance frankly avowed, for example, by Roman Catholicism, is the church's responsibility as the custodian of the eternal and unalterable truth on which the destiny of man in the next life depends. A religious institution claiming universal validity and essential changelessness for its doctrine of salvation is necessarily intolerant. It is a self-evident duty for such an institution to give no quarter to conflicting views, since any conflicting view tends, if the initial premise be accepted, to corrupt true religious belief and thus to endanger

man's immortal soul. "The Church of Christ," said St. Augustine, "persecutes in the spirit of love . . . that she may recall from error . . . to secure the eternal salvation" of her enemies. Wherever doctrine becomes more responsive to growing human experience, religion becomes tolerant in spirit as well as in practice, but institutionalized religion suffers correspondingly in authority and power. Any religion therefore which is based upon correctness of theological belief is forced to adopt St. Augustine's position of *nulla salus extra ecclesiam* and in dealing with heretical opinions is forced to act on the principle that might makes right. The successors of St. Augustine in the mediaeval period could therefore be single minded and blunt. They were sure of their ground, and complete certainty fosters unabashed intolerance; they were unhampered by the prevalence of humanitarian feelings from carrying out extreme measures of repression; and they were provided with adequate social machinery for making their intolerant will effective.

The theoretical justification of political intolerance has varied with the conception of the state. In pagan Rome wide tolerance of belief was permitted, but the state was unyielding in its demand for participation in the imperial rites, which was in a sense an oath of allegiance. Marcus Aurelius, renowned for his intellectual and emotional liberality, prosecuted intransigent Christians because they refused to recognize the sacred character of the Roman emperor, a refusal which threatened to undermine the foundations of the state. With the establishment of the Christian empire the state became in theory the secular arm of religion and throughout the Middle Ages was expected to enforce the dogma of the church. In the early modern period the absolute state adopted the right, formerly exercised by the absolute religious institution, to insist upon uniform belief in all matters involving the stability and cohesion of the polity. A further development of the state idea, necessarily linked with intolerance, is illustrated by pre-war Prussia and present day Italy and Russia. Here the state is conceived as having a moral end to serve and becomes imbued with a Messianic sanctity. In all these instances the basis of intolerance derives from the assumption that a selected set of values either by its very nature is not or for practical reasons must not be subject to revision. The canonization of the will of the people in democratic rhetoric has made prevalent a type of

intolerance even more devastating in its potency than the intolerance of an absolute ruler or of an autocratic dictator. As Lord Acton has pointed out: "It is bad to be oppressed by a minority, but it is worse to be oppressed by a majority. For there is a reserve of latent power in the masses which, if it is called into play, the minority can seldom resist. But from the absolute will of an entire people there is no appeal, no redemption, no refuge but treason."

Not only the church and the state but any political, military, social, economic, educational or religious group having a program to forward or a vested interest to protect may become intolerant and if in a position to do so may attempt to suppress all manifestations of divergence. But whatever the nature or the source of the intolerant disposition, it enters the militant stage only when the values accepted as ultimate are felt to be actually in danger. An important factor in all persecution is fear. Even the religious persecutions of the past for all their appeal to eternal truth and their zeal against error as a spiritual disease did not take violent form except when intellectual or economic developments aroused lively fears for the prevailing religious system. It could be argued that intolerance unassociated with a fear complex of some sort is from the social point of view quite negligible.

The World War, which liberated a host of fears on the world, marks the beginning of a strong accentuation of militant intolerance; just as the subsequent fluctuations of intolerance reflect ups and downs in the apprehension of danger to social, political and religious institutions. For a considerable period prior to 1914 the civilized world was comparatively tolerant. There was good ground for John Morley's opinion, expressed in the 1870's in his book *On Compromise*, "that the right of thinking freely and acting independently . . . is now a finally accepted principle in some sense or other with every school of thought that has the smallest chance of commanding the future." This optimism, shared by many of Morley's contemporaries, has given way in the post-war period to a growing skepticism even in England and still more in those countries where the march of events gives support to Mussolini's dogma that the road to progress lies "over the more or less decomposed corpse of the Goddess of Liberty." In the United States too a retroactive tendency has been gathering momentum. The

passing of the illiteracy test over President Wilson's veto, deportation processes, criminal syndicalist laws, anti-evolution legislation, special oaths of national allegiance for teachers, the decision of the United States Supreme Court (October term, 1930) to the effect that the expressed will of Congress must be accepted as harmonious with the will of God and the like are indications of a movement toward cultural uniformity by coercion.

To deal constructively with the problem of intolerance is obviously difficult. No institution or organized group having adopted a program of action can afford to turn aside to consider any and every counterproposal. Successful administration of a social scheme is impossible without a kind of blindness to criticism. In this sense the refusal to tolerate is inevitable and useful, but as already indicated this is not intolerance in its stricter meaning. Adherence to a program turns into intolerance when the program becomes an end in itself and the uses to be served by the program are a secondary consideration. And "the uses to be served" are in their turn instruments of intolerance when as objectives of action they are looked upon as the final court of appeal in disregard of the living urgency of experience. If education in and out of school can develop a general understanding of ideals, customs and institutions as tentative means in the search for happiness, means to be freely tried out yet always subject to revision at some point by reference to the course of everyday life, education will greatly aid in overcoming intolerant inclinations. And in so far as such institutions as the state, the church and the school can more obviously and more effectively secure what must be gained through co-operative effort, the reason for the fear which has been and remains one of the chief causes of intolerance will have been removed. But the most important reform is also the most difficult to accomplish. According to the conventional conception of society, especially as this is entertained by dominant educational, religious and political groups, the mass of men must be cut from the same cloth. The ideal is adherence to a common pattern. A genuine or positive tolerance of spirit, on the contrary, would lay down as the basic social principle the intrinsic importance of individual differences. In a society which aimed at uniqueness in its citizens rather than at sameness, although in the process it would create for itself other problems, the evils of intolerance would tend to be eliminated

and the dangers of mediocrity and standardization greatly minimized.

INTRANSIGENCE entered as a term into social and political theory in the year 1873 when Spanish republicans put through a revolution and set up a democratic government. The constitution written for their new republic did not suit the radical section of the revolutionary party. They refused to accept it and turned a cold shoulder to every proposal that fell short of their demands. Their stand created an impasse, which was one of the conditions that led to the restoration of the monarchy. It was described as intransigent and for some time the political radicals of the Latin countries of Europe were called intransigents.

The attitude of mind which is designated by the name is, however, by no means restricted to radicals. Intransigence is a typical and recurrent phenomenon in the life cycles of societies and is found indifferently among any company of extremists. On the whole it has been somewhat more persistent among conservatives and reactionaries—such as the loyalist adherents to the house of Stuart in England, the Carlists in Spain, the royalists in France—than among radicals. Its attribution to radicals is an accident of the fact that it was in a radical situation that the attitude first received its identifying name. The name applies to any person or group which refuses to compromise its principles or arbitrate its demands, which rejects the adjustment of differences or the conciliation of disputes. The intransigent takes his stand upon the principle of "all or nothing," "rule or ruin."

In the social process such a stand rarely develops as a healthy or intelligent one. It presents itself in the form of a counsel of perfection, but its roots lie commonly in a mood of despair. The mood is hardly ever conscious. Its stimulus may be some not too obscure individual diathesis, like Savonarola's; or it may be a feeling of impotence and frustration in the presence of insuperable social facts. Whatever the stimulus, a program is formulated to alleviate the unrest it arouses. If the times are unstable, if many feel uncertain and insecure, this program becomes a focus of equilibration for a group. The group comes together, debates, analyzes, refines, reformulates. In the course of time an organic doctrine takes shape which has established itself as the ruling passion of the group, with all the authority and ineffability of a religious revelation, to be set up as an imperium over all the people. If the particular national or ecclesiastical economy where this is happening continues to disintegrate and the mores loosen, the group with the set doctrine and discipline may be able to seize power and apply its doctrine as a program. When this happens it finds that to retain its power it must compromise its principles. If it fails to compromise it is defeated. The effect of defeat, however, is not an abandonment of the doctrine but an intensification of faith. The validity of the doctrine increases as the power and importance of its adherents diminishes. Every practical setback is compensated for by an enhanced theoretic affirmation. The affirmation becomes in the course of time the compensatory corrective to every feeling of inferiority or deficiency from which the affirmer suffers. *In hoc*

signo is his sense of personal dignity and worth preserved and victorious; he must hence affirm it regardless of consequences.

Intransigence thus involves all the stigmata of a religious cult. Its doctrines with their commentaries and interpretations become tantamount to a theology. Their role is to serve as rationalizations of the discontents of their believers. Once formulated and fixed, such rationalizations become the special tradition of a group and are passed by emotional contagion and doctrinal schooling from one generation to another. They gain when so transmitted a liturgic and ceremonial significance. And this constitutes their vital function; by its means they survive even when they contain an aggressive component which leads their devotees—as is so often the case, for instance, with the *Camelots du Roi* in France—to clashes with the police power of residual society.

Often the entire response of an established order to its intransigent minorities is occasional action of the police. There are several reasons. To begin with, the mere definition of their principles and the ordination of their practises serve to drain and to relieve the implicated feelings of intransigent associations. Again, their small numbers, the exclusiveness of their "mystery" and their consequent supercilious attitude toward the uninitiate and profane who neither acknowledge their doctrines nor admit their disciplines all help to expand their self-feelings, until they gain without further action a sustained sense of personal adequacy and even of superiority. Radicals and conservatives alike make themselves, by means of their intransigency, in their own eyes a company of the elect which promulgates right rules but bears no responsibility for applying them.

Avowed religious cults manifest these traits of the intransigent in their sumptuary practises, their diet and their dress—such as the *Kashruth* of orthodox Jews, the prescriptions and tabus by which Gandhi and his sect govern their personal habits, the buttonless garments of the Mennonites, the uncut and unshaven head-pieces of the Seventh Day Adventists and the practise of marriage and divorce of the Roman Catholics. The prohibition movement in the United States is allied to these by mood and sanction; so are vegetarianism, antivivisectionism and various health cults. The domain of political and economic organization offers such types as the legitimist cults already referred to of France, Spain and England. American com-

munists as compared with Russian are intransigent. So are the Industrial Workers of the World in the labor movement. So are extreme pacifists. So are all anarchists. In all these cases the intransigence develops as compensation for feelings of inferiority set up by some perhaps unrelated situation. Thus the doctrine and discipline of Jewish orthodoxy compensate the persistent failure of the Jews to realize their national aspirations. Defeated in those, they define themselves as a chosen people whose election is signalized by peculiarities of dress and diet, by priestly peculiarities made common to a whole people. Similarly the principles and practises of the royalists of France offset the obvious ludicrousness of titles of nobility and courtly ceremonial in a bourgeois republic of petty tradesmen, rentiers and farmers who have abolished monarchy and all its impedimenta. Prohibition, which when bona fide is mainly a woman's gospel, provides a somewhat secularized channel for the emotions of the genteel tradition whose sectarian manifestations get belittled and nullified by the harsh realities of changing American society with its pioneer standards and industrial economy.

Prohibition in the United States is an intransigency which has come to power and has been compromised, but not by its honest adherents. As a rule it is the leaders of the intransigent group themselves who under the weight of responsibility which comes with power abandon rationalizations for reasonableness, principles for policy and ceremonial for purposive action. The history of communism in Russia provides the great current example of a substitution of this type, as the record of Christianity in Europe provides the great historic one. But rarely does intransigency happen into power. In the main its influence in the socio-political process is a function of its powerlessness. Powerlessness leads to the elaboration and refinement of doctrine and to ceremonial or symbolic action. The latter is dealt with, if at all, by the police; but the former operates by distortion and contagion. Its systematic completeness and logical rigidity make of it almost automatically a focus of attack. It becomes to its opponents a surrogate for the devil of orthodox theology. They incarnate in it their own fears and discontents. So royalist salvation is republican damnation; communist heaven is capitalist hell. Socialist, communist, Bolshevik, mean in America what bourgeois or capitalist would mean in Russia if such a group were free there to publish principles and pro-

gram. But attack imposes attention to the enemy, calls for information concerning his abilities and weaknesses. The required attention distorts the direction of the processes of the majority; the needful information contaminates its purposes. If the intransigency is of sufficient prestige and loud enough it remains unchanged in itself, but it has considerably modified the residual social process. This is the case with royalism in France and Catholicism and communism almost anywhere in industrial Europe. Where the intransigency lacks prestige it remains an irrelevancy and is left behind in the backwash of social change. This is the case with most of the lesser religious cults.

INVENTION. A sharp distinction is often drawn between invention and discovery; the former is defined as an active combination of social elements into a new form, the latter as a more passive perception of existing relations of such elements. The two processes are, however, closely interrelated. Discovery of new facts or laws in physical or mental nature presupposes the invention of new methods of acting or thinking; on the other hand, invention of new influences and reactions whether in nature or in society is rarely devoid of newly discovered facts as assisting, inspiring or even originating its conditions. Invention in contrast to discovery is usually thought of as a change founded on or culminating in a new or altered technical process, in the sense of a combination of physical or material factors. However, there are also the "moral" inventions stressed by modern French sociology; Gabriel Tarde rightly balanced the conservative and collective forces of social imitation against the innovating and individual forces of social invention. Social scientists must reckon with mutations as the casual appearance of new data in a given combination of interrelated phenomena; their research in causation is able only to analyze the conditions under which man's creativeness reacts to or furnishes such new data.

Inventions may grow out of fixed situations and habits by imperceptible degrees, principally through the continuous summation of a large number of small deviations from initial situations and habits. In such cases, which are preva-

lent in primitive as well as in modern industrialized mass society, as has been shown by Lester Ward, Lloyd Morgan and others, the difference between invention and imitation is reduced to a minimum. The momentum of the change is overwhelmingly on the side of collective action; the singularity or heroism of invention and inventors is negligible.

Modern and primitive societies also furnish examples of a strong preeminence of the creative and voluntary element in both the origin and the elaboration of the inventive process. The instincts of workmanship and of leadership cannot be severed from the emergence of technical or non-technical invention; the whole process of invention becomes in consequence at once more irrational and more rationalized. Recent ethnology shows that heroes are not always legendary symbols of collective change. Modern technical invention as a commercialized branch of the division of labor also appears to serve a system of social wants which may be taken for granted by modern man but as a whole hardly admits of a rational explanation.

The two aspects of invention might seem to be another statement of the ethnological controversy between evolutionism and diffusionism. But the relation is at best an indirect one. Diffusionist conceptions are strengthened when it is recognized that a good deal of inventive change has definitely been introduced into static societies from outside. On the other hand, it will be well to regard the concept of a static society as a negative rather than a positive one and to ask what is to prevent cumulative progress through evolution. Scientific appreciation of social change by invention demands patient empirical research into the series of factors whose interrelation determines the fate of invention in human society. These factors are the character of real or personal data acting as initial mutations and the character of the natural and social systems and organisms that respond to those stimuli actively or inactively, rationally or irrationally, consciously or unconsciously. The traditional method of logical or psychological speculation on the origin of technical principles, such as the wheel and the screw, must be replaced by the collection of data on the different milieus and moments of their first historical or prehistorical appearance.

In the history of civilization Greek society was the first to exhibit the signs of technical and "moral" invention in the more discontinuous and explosive form of its sophism and idealism.

Greek mathematics and physics have provided all later civilizations with the fundamental material for social and scientific construction and reconstruction; the manner in which invention was here anticipated for centuries has provoked justified wonderment. Greek culture has served as a principal basis for theories of the inventive process that emphasize the difficulties encountered by inventions in a politically and economically static society and the dependence of the spread and development of inventions on a parallel evolution of the whole social body. One of the striking incidents in the history of technology is the precocious advance of Greek scientific theory toward revolutionary inventions, such as the steam engine and pneumatic artillery, and the arrest of this advance not so much by social checks or prohibitions directed against it as by the limited and unimportant uses to which it was put: the utilization of steam expansion in Hero's steam boiler and of the same great physicist's anticipation of Percival Everitt's automatic seller for the religious purpose of distributing holy water are pertinent examples. But it is precisely these positive instead of negative deflections of inventive processes that warn against laying too great and one-sided stress on the materialistic conception of social conservation as a result of undeveloped productive forces. It would be just as legitimate to conclude that the tremendous outburst of human intellect represented by Greek civilization was devoid of far reaching social and economic consequences because it was insulated by the economically neutral city-state and its aristocracy; this very economic sterility may have contributed to Greek intellectual precocity.

Mediaeval society erected under the auspices of the Roman church the static equilibrium of social strata and of economic existence within these strata into an ideal of sufficiency. Even if reality did not always and everywhere correspond to this ideal, its tendency clearly discouraged violent inventive progress in reference to both supply of and demand for economic goods and services; similarly it discouraged new mental and moral views and attitudes that might have stimulated technical invention. On the other hand, there was not only the underground devotion to ancient intellectualism both in ecclesiastical tradition and in the Arabian Aristotelianism and empiricism that was like a surf all along the southern border of mediaeval Christian culture; there was also, as modern research reveals, a slow cumulative growth of

empirical observation in the various scientific fields connected with mediaeval arts and crafts, such as medicine, mining, fishery and nautics. It is probable that the outward triumph of the Renaissance was less of an original landmark and more of a sudden sprouting of germs after long incubation than traditional conceptions would have it. In some respects the scientific urge of the Renaissance, bound up with the mystical intuition of alchemy and astrology, must in a sense have exerted a restraining influence upon extreme innovations that are taken too widely. From this viewpoint the theory of Max Scheler that the church was fundamentally friendly toward scientific discoveries and innovations and that it combated in Giordano Bruno and later in Galileo not so much the scientific kernel as the metaphysical setting of their doctrines loses its *prima facie* paradoxical character. The new monastic orders of Franciscans and Dominicans, as they made for a spiritual and moral intensification of the Christian religion, brought forth theoreticians and inventors of the rank of Robert Grosseteste and Roger Bacon; and the Copernican revision of the Ptolemaic astronomical systems was more or less anticipated in the school of Ockham at Paris.

* The role of invention in the form of technical and social change in modern Europe is, however, as unique in the history of mankind as is the contemporary advent of "capitalistic" economy; the two may be taken as different aspects of the same great transformation of the western world. The underlying principle of this transformation is the changed attitude of man to his natural and social surroundings, from the acceptance of a given state and order of things to an ever growing determination to use—and belief in being able to use—discovery as a means of altering and adapting the environment to the fulfilment of new wants and plans. This changed attitude, which conceives of science as an instrument for making and remaking a universe of one's own, seems to contain the secret of the European's ultimate political ascendancy over the older civilizations of Asia. It alone was able to hold down the dangers of Mongol and Islamic invasion and in turn made western Europe the center of discovery, colonization and economic integration of all the outlying continents. "Moral" inventions were henceforward directed toward extending the circle of rationalistic enlightenment to an ever wider range of groups and strata inside as well as outside this cultural center, under the political and social concept of modern democ-

racy, while scientific and technical inventions have been advancing on parallel lines with the object of exchanging production and consumption in ever widening markets. Hence the parallelism of periods of political and industrial revolutions (mostly with a certain lag of the latter) led by England in the seventeenth and taken up by America and France in the eighteenth century. As every political revolution is the emergence of tendencies and forces long accumulated in a social and political situation but has distinctive causes and characteristics of its own, so revolutionary epochs of modern technical invention show extended and collective effort toward the solution of certain productive problems and sudden and individual intensification of this effort. The leading inventions of modern industry, those of the textile trades and of metallurgy and chemistry, had been anticipated experimentally and economically from the time of the arrival of capitalistic enterprise in the fifteenth and sixteenth centuries. But only their condensation in the shape of a few definite solutions, called forth by peculiar social and economic situations, enabled them to revolutionize modern economic life and to assign definite evolutionary power and place to the principal capitalistic nations, England, France, the United States and Germany. Made possible by an exceptional combination of transport facilities and mineral wealth, the heroic age of English industrial invention was opened by the pressure of world demand for English yarns and cloths, the mechanical fabrication of which in turn stimulated puddling and coke production as a basis for the new textile machines and steam engines. Invention in France was applied rather to the artistic refinement characteristic of its special function in the international division of labor. Eli Whitney's cotton gin and McCormick's reaper were as peculiar to the economic demands of the United States as Fulton's and Ericsson's work was to the shipping and shipbuilding trades. Germany fructified the inheritance of French chemistry and English iron smelting in the inauguration of the latest stage of industrialization, that denoted by the branching out of modern coal industry into the gigantic networks of the chemical and electrical industries.

The biographic history of these inventions also betrays the duality of collective atmosphere and individual inspiration, of the genius and the quack, of inventors and money makers. If the theory of economic motivation has tended to exalt the psychology of inventions above that of

industrial enterprise as a kind of earnest of a more altruistic future of society, it seems to have overlooked in a too rationalistic way the fundamental relationship between the two; namely, the ultimately irrational will to power that urges both the apparently disinterested work of scientific and the apparently acquisitive work of economic conquest. In historical perspective the two are coordinated products of the machine age, in so far as even in the case of the most independent pioneers it is the technical and economic urge of the age rather than any conscious motive or set of motives that furnishes the background and presupposition of their activities.

In the economy of the capitalistic market there has also been some inclination to idealize the inventor as the humanly more valuable but economically helpless or inferior object of exploitation by business. Without minimizing the representative importance of the many cases that have realized this pattern one may draw attention to the fact that an extreme individualistic view obscures the laws of interdependence between the inventive genius and economic society. Invention, like all other situations of "opportunity cost," contains at least an element of potential monopoly, the existence and execution of which depend largely on the whole body of surrounding social institutions. The prevailing form of this dependence is social protection awarded to the inventor—from the magic secrecy of early procedures and discoveries to the patent and copyright laws of modern civilized nations and to international treaties. It is significant that the first introduction of patent laws in early Stuart England was closely bound up with the mercantilist monopolies so objectionable to economic liberalism. The individual fortunes made under patent laws by inventors or applicers of inventions are frequently balanced by the fortunes lost in obtaining and defending the grant of a patent. The possible retardation of economic progress by individual authorship rights has its counterpart in the apparently frequent practise of capitalistic business of buying up inventions for the purpose not only of preventing untimely losses in productiveness but also of keeping up monopolistic situations. In the case of major inventions involving new industrial developments the tendency of modern business toward ever increasing size and concentration of plants explains the tremendous difficulties and risks involved in the step from the most perfect technical elaboration of an idea to its most modest economic application. The latter is governed not only, as is com-

monly supposed, by the laws of cost and supply prices but in a much more precarious manner by elasticities of demand that play the most surprising tricks even under a "dictatorship of the producer," as exhibited by modern standardized mass societies. On the other hand, the directed invention, which has come to take such a prominent part not only in the laboratories and the experimental studies but also in every other department—from personnel to marketing—of modern rationalized industry, has to a large extent exchanged the creative and individual for the cumulative and collective function and therefore the entrepreneurial for the executive labor character. This development has raised new and difficult problems of both internal remuneration and external commercial law: for example, in the question of the betrayal of business secrets to competitive firms.

The historically unique character of the modern age of industrial invention in the western world is best shown by the signs of a change or at least a division of public opinion on the social desirability of the continuance of technical progress at the present rate of increase. The sentiments prevailing in the early decades of last century, when not only the revolutionary workmen of the Luddite movement but even a leading theorist like Ricardo came to despair of a smooth working of the "law of compensation" for loss of employment caused by the increased production resulting from the introduction of machinery, repeat themselves a hundred years later. Technological unemployment has become a favorite reproach chiefly of socialist economists against what appears to them the incapacity of the capitalistic system to maintain proportions between technical progress and its rationalizing effects on production and consumption. The "law of compensation" can today no more than a century ago be regarded as an automatic process. On the contrary, the increase of the national and international complexity of modern industrial society makes adaptation to technical progress a series of equations with an increasing number of unknowns. Empirical research has made little progress toward the solution of the problem of the normal introduction of technical revolution into the apparatus of modern production. It has not determined whether or to what extent capital for rationalization purposes is taken away from other enterprises; nor has it revealed the proportions between negative rationalizing as cost saving and positive rationalizing as expanded production, between primary unem-

ployment created in the rationalized industries and secondary unemployment created in the industries that used to supply the primarily unemployed—that is, between the gain in physical productive power and the loss in purchasing power of the masses of a society, not to speak of the changing conditions of money and population. The planned economy of a communistic state might on principle do much to remove friction and accelerate adaptation between these various elements. But at least under the peculiar conditions of the Soviet government proof has not yet been given that this principle makes much practical difference, because even the complete dictatorship over labor and capital claimed by this government has not yet removed the enormous disproportion between a strangled national consumption and a forced investment of capital into a huge apparatus of industrialized production.

While societies like those of the United States and Russia continue to believe in progress by unchecked technical and other invention, because they believe either the harmony of the market or the dictate of economic plans will be able to make the ends of the social product and the social income meet, some skeptical social scientists question either the blessing or the possibility of such unchecked progress. They ask whether this progress in continuing to replace physical and mental "nature" in society by the artificial structures of an invented world might not dry up the sources of creative force that underlie even the most rationalized and collective inventing. They further inquire whether there is logic in the assumption of an endless rectilinear technical accumulation and whether a static state of equilibrium can be evolved out of a series of processes inherently dynamic. They point to the possibility that political or economic catastrophes may befall the domination of the world by the western nations through the agency of racial or economic outsiders, or that the genius of the western nations may turn away from the inventive period of the last few centuries, backward or forward to other forms of activity and symbols of desire. But such possibilities of inverted progress cannot be deduced from any actual data of the present situation in modern scientific thought, when even the program of world revolution leaves unshaken the factor of technical progress in the older conceptions of economic society.

INVESTIGATIONS, GOVERNMENTAL.

The term governmental investigations might be interpreted broadly to include every attempt on the part of a governmental agency to secure information of any sort whatsoever—even the research and investigations of a scientific, commercial, agricultural or similar character which are constantly being conducted by various departments of government and attempts by the department of justice or the police to solve particular crimes. It is perhaps more valuable, however, to limit its meaning in this connection to inquiries conducted by ad hoc bodies or by permanent bodies empowered by some definite statute, resolution or order to investigate some particular problem of public interest. Governmental investigations may be motivated by several distinct purposes: to assist legislative bodies in judging of the elections, returns and qualifications of their members; to effect legislative or executive supervision of the administration; to secure information to aid in framing new legislation, amending old laws or voting appropriations; and to determine the causes of particular events, for example, military defeats, industrial disputes or business depressions. Investigations may serve also either incidentally or even primarily to inform public opinion regarding the matters under inquiry. With the growth of governmental powers, the widening of the suffrage, the increasing democratic control of government, the development of new means of communication and the widespread dissemination of education this informing function has become more and more important.

Inquiries are customarily conducted by legislative or administrative committees or commissions; but in relatively rare cases, such as the inquiry into the magistrates' courts of three counties in New York City during 1930-31 by the Appellate Division of the Supreme Court, they have been committed to judicial bodies. The question as to which agency shall undertake an inquiry has at times assumed considerable im-

portance. In the struggle for parliamentary government in Prussia, Germany and Austria in the latter half of the nineteenth century the demands of the legislatures for their own investigations were several times checkmated by the creation of royal special investigating committees composed entirely of members appointed by the governments or of such persons and members of the legislatures. By setting up the Dodge Commission President McKinley similarly forestalled congressional investigation into the conduct of the Spanish-American War, the only war engaged in by the United States which was not investigated by Congress.

In Great Britain and the United States the investigating committee or commission generally proceeds by holding hearings, after due notice, at which persons believed to possess relevant information are invited, requested or summoned to appear and testify. In France and Germany, while the method of oral hearings is employed, greater reliance is placed on other methods, such as distribution of questionnaires and analysis of statistical samples. Increasing use of these methods is being made by English speaking countries.

Effective utilization of the method of oral hearings rests fundamentally upon the power to summon witnesses, to compel testimony, to require the production of books and records and to have recalcitrant witnesses punished for contempt. Such power is not possessed by ordinary legislative committees, although they may conduct hearings on a voluntary basis for the purpose of determining the opinion of the public as a whole, of experts and of interested parties on proposed legislation. For special tasks, however, the legislature may endow such committees or ad hoc bodies with the power to summon witnesses and require the production of papers. Royal commissions of inquiry in Great Britain can exercise enforcing powers only if specifically granted them; departmental commissions do not receive such grants. Congress generally gives the power to investigating committees in the act creating them, except in cases where the purpose is solely educational, as in the inquiry conducted in 1931 by the United States Senate Committee on Manufactures upon the proposal for a national economic council. Similarly temporary fact finding commissions in the United States are rarely given enforcing powers, although permanent administrative bodies with investigative functions, such as the Interstate Commerce Commission and the Federal Trade

Commission, are generally vested with compulsory testimony powers within limits. The investigating body cannot itself punish disobedience but it can generally call upon the regular organs of justice or, in the case of legislative investigations, upon the house which created it, to punish recalcitrant witnesses.

Investigating committees empowered to compel testimony are not bound by all the principles or precedents of courts of law regarding the privileges of witnesses or the giving of testimony. The witness in the United States has no inherent right either to give evidence in his own behalf or to be advised by counsel or to cross examine his accusers. There has been a growing tendency in recent years, however, to allow witnesses greater liberty to consult counsel; and committees usually permit counsel for any interested person to cross examine witnesses. Although investigations are not criminal cases, the only privilege which Congress has generally tended to recognize is that guaranteed by the Fifth Amendment to the constitution—that "no person shall be compelled in any criminal case to be a witness against himself." In order to secure testimony without violating the amendment Congress in 1857 passed a statute denying persons the right to refuse to give incriminating testimony but granting them immunity from any prosecution in connection with the acts testified to. Similar legislation was enacted by the legislature of New York state in 1931 in order to facilitate the work of the Hofstadter Legislative Investigating Committee. Congress, however, after seeing confessed corruptionists escape prosecution through their testimony amended the law in 1862 to provide that witnesses in congressional investigations must give testimony even though incriminating, but that their testimony or private documents produced by them could not be used against them in subsequent prosecutions. Samuel Seabury, counsel for the Hofstadter committee, attempted to escape the same difficulty by refusing to permit important officials suspected of corruption to testify unless they signed a waiver of immunity. The House of Representatives has at times indicated, although never in precise terms, that some of the "guaranties of a fair trial" apply in investigations preliminary to impeachment proceedings. In Germany also a distinction has been made between investigations whose object is criminal or disciplinary action and those merely incidental to legislation; in the former the privilege of refusing to give incriminating

testimony is recognized, but not in the latter. France apparently provides the least protection to witnesses before investigations; England, on the other hand, has in the Witnesses Protection Act of 1892 gone furthest in the other direction.

In France hearings are private; most other countries provide that they be public unless a majority of the committees votes otherwise; in the United States, while they may be either public or private, the tendency in recent years has been toward publicity. Publicity aids the committee by informing and arousing public opinion. In the Hofstadter Legislative Committee investigation into the government of New York City in 1931 and 1932 private hearings before a single committee member were used to obtain information later presented in public hearings before the committee as a whole. The power of committees to designate subcommittees of one or more to hear testimony is generally recognized, but such subcommittees do not generally have the same control over persons and papers as the full committee, unless specifically granted by the assembly.

The right of investigating bodies to hold meetings and take testimony at places other than the seat of government has now been generally established. Congressional committees in the United States may hold hearings during or between legislative sessions, at the committee room in Washington or elsewhere. In senatorial election years the Senate usually appoints a special committee to investigate campaign funds, which holds hearings in various states.

Investigating committees usually have the right to report at any time; they may make interim or progress reports and a final report upon the completion of the inquiry. Both majority and minority reports will be filed if the members are not unanimous. The assembly as a rule orders reports of its investigating committees printed together with the minutes of the hearings, which often fill several volumes. More than 11,000 printed pages emerged from the hearings of the Senate and House committees on the coal problem during the Sixty-third to the Sixty-seventh Congress, inclusive. Reports of British royal commissions are printed as parliamentary papers; those of American fact finding commissions are generally printed by Congress but sometimes by quasi-public agencies. The reports of investigating committees are invaluable for an understanding of the social, economic and political history of the countries concerned.

The power of legislative assemblies to institute investigations and to endow its investigative bodies with the power to compel attendance, testimony and the production of books and records was first established by the English House of Commons. A legislative committee of inquiry vested with this power was used in the House of Commons in disputed election cases as early as the end of the sixteenth century. There are records of many subsequent election investigations. The earliest grants of investigative power to parliamentary committees and their enforcement by the Commons as part of the legislative process and to determine the legality of expenditures also occurred in the seventeenth century, especially after 1688. Innumerable instances of inquiries since that time, of orders for the attendance of witnesses and of punishment for disobedience have definitely established the broad investigative powers of the House of Commons. In *Howard v. Gosset* [(1845) 10 Q.B. 359] Lord Coleridge said that the Commons could inquire into "every thing which it concerns the public weal for them to know; and they themselves, I think, are entrusted with the determination of what falls within that category. Coextensive with the jurisdiction to inquire must be their authority to call for the attendance of witnesses, to enforce it by arrest when disobedience makes that necessary" The power to commit for contempt contumacious witnesses before committees of investigation has been recognized and sanctioned by judicial decision as an inherent and indispensable auxiliary of the legislative power, without which the Commons could not perform its legislative and supervisory functions; just as from ancient times legislature and courts have exercised the power of summary commitment, for reasons of necessity and self-defense, to deal with libel and slander or with breaches of their privileges.

The importance of legislative investigations is declining in England because of the development of more permanent means of performing their functions. Since 1868 election contests have been tried in the courts. Since 1832 Parliament has placed increasing reliance upon royal commissions to make inquiries preliminary to legislation. These commissions are agencies of the executive and they enjoy a longer tenure and are composed of a more impartial and expert personnel than legislative committees. Most of the great English social reforms have resulted from their investigations. They do not have enforcing power unless specifically granted by Parlia-

ment. The British Treasury uses departmental and interdepartmental committees to supervise and control the financial affairs of the several services; such committees, however, cannot compel testimony. Since 1866 the Commons has received complete reports from the comptroller and auditor general on the manner in which its grants have been expended. Since 1861 the Standing Committee on Public Accounts of the House of Commons has been a critic of Treasury administration, and by reporting its findings to the Commons has fastened financial responsibility on the executive. Several additional sanctions for enforcing ministerial responsibility to the Commons reduce the need for committee investigations: "grievance before supply," the daily parliamentary question hour, supplementary questions, debate on the motion for adjournment and on the address in reply to the speech from the throne, and votes of censure. The composition of investigating committees of the House of Commons is as a rule non-partisan, and almost invariably their work is concerned with the determination of questions of fact or with the formation of judgments based on facts and the opinions of experts. The British select committees are not intended to be the tools of party tactics and party fights seldom occur.

The inquisitorial power was assumed by the American colonial assemblies, which modelled themselves after the House of Commons and asserted the same privileges. The contempt power was conferred upon all colonial legislative bodies as an essential auxiliary of the legislative power and without specific provisions. The records of the thirteen colonial assemblies, the practise of the Continental Congress and the committees of investigation of the state legislatures in the period following the revolution furnish ample evidence of the effective transfer of this institution to American political practise. In the course of their existence state legislatures have authorized thousands of investigations and have equipped their committees with the contempt power, which with rare exceptions has been upheld by state courts. At least ten state constitutions now provide specifically for this contempt power; some states do the same by statute.

The federal Congress, which began to function in 1789, also assumed that the legislative power implied the use of committees of inquiry with power to send for persons and papers. The first investigation by a committee of the House of Representatives with such power concerned

the defeat of General St. Clair in the northwest in 1792; the duty of the House to guard all public expenditures was cited as justifying this procedure. The first Senate committee inquiry under a grant of power to call for persons and papers took place in 1818 and dealt with the conduct of the Seminole War in Florida. Military affairs and operations were thus the object of the earliest investigations by the United States federal government, and they have been the object of more such investigations than any other single subject. Committees of inquiry had been employed to investigate the conduct of administrative departments and officials a number of times before 1827. In that year for the first time a standing committee of the House was given power to call for persons and papers in order to investigate the effect of a proposed revision of tariff duties upon domestic manufactures. This was the first congressional investigation as a preliminary to legislation. Investigations of the qualifications, behavior and immunity of members have been conducted upon occasion by committees in both houses. The first joint committee of both houses was created by a resolution passed in December, 1861, to investigate defeats of the Union armies.

About 285 investigations of the executive were completed by select and standing committees of the House and Senate from 1789 to 1925. Only three Congresses have not instituted such investigations, while no administration has been spared. A high watermark was reached during Grant's eight turbulent years, when Congress undertook thirty-seven inquiries into the administration; but this was surpassed in Wilson's last two years, when fifty-one congressional investigations either of the executive or to secure information were authorized. The total number of congressional investigations concerning members or the federal judiciary or collateral to the lawmaking function probably runs into the hundreds. Landis gives an incomplete list showing forty Senate inquiries between 1818 and 1923, thirty-eight House investigations between 1792 and 1892 and fourteen joint investigations between 1861 and 1922 by committees empowered to send for persons and papers.

On various occasions hostile witnesses have challenged the power of Congress to punish for contempt their refusal to testify or to produce papers. In 1857, after a newspaper correspondent refused to answer questions put to him by a committee appointed to investigate published

charges of the corruption of members, Congress in order to fortify itself in the exercise of the inquisitorial power provided by statute that a person who is summoned as a witness and who fails to appear or refuses to testify shall be punished by fine or imprisonment. The fact of contumacy was to be certified by the speaker of the House or the president of the Senate under seal to the district attorney of the District of Columbia. This act was upheld by the Supreme Court in the Chapman case [166 U. S. 661 (1897)]. Except for the single case of *Kilbourn v. Thompson* [103 U. S. 168 (1880)], in which the Supreme Court adopted the view that the contempt power of the House of Commons is judicial in character, derived from the time when Parliament sat as a high court, and is hence not exercisable by a legislature deprived in its creation of all judicial functions, the Supreme Court has affirmed the contempt power of Congress within the limits of its legislative power. The constitutional status of the congressional power of investigation was not finally settled until in *McGrain v. Daugherty* [273 U. S. 135 (1927)] the court held that the power of inquiry, with enforcing process, is an essential and appropriate auxiliary to the legislative function; that a legislative body cannot legislate wisely or effectively in the absence of information; that an inquiry to obtain information in aid of the legislative function, even though this purpose is not avowed in the resolution ordering it, is proper; and that a witness rightfully may refuse to answer where the bounds of the power are exceeded or the questions are not pertinent to the matter under inquiry. This decision was later reaffirmed in the *Sinclair case* [279 U. S. 290 (1929)].

Refusal to testify before a congressional investigating committee thus exposes a witness to three risks. If the committee takes no action against him, he will be left under suspicion. If it summons him to the bar of the house which created it, he may be committed to jail for contempt for a period not exceeding the duration of the current Congress; but he can obtain judicial review of his case through a writ of habeas corpus. If the house refers the case to the district attorney, he may be criminally prosecuted under the act of 1857. On the other hand, a rebellious witness may, like Mally S. Daugherty, escape punishment altogether, even if the highest court decides against him, through the prior termination of the life of the select committee whose questions he refused to answer.

Both the right of Congress to make legitimate inquiries without interference and the right of privacy of witnesses appear to need further protection, but only a voluntary reform in methods of conducting inquiries is likely to bring this about.

Before the Civil War inquiries were more frequently authorized by the House of Representatives; but since that time the Senate has been the more active body. This change has been ascribed to the control of party leaders in the House; to the fact that the House is more likely to be in political agreement with the president, especially during the first half of a term; to the freedom of debate and absence of effective closure in the Senate; and to its more frequent lack of political harmony, a result of the presence of the holdover members or of a group of insurgents.

In recent times congressional investigations have ranged over a wide area. Committees have delved into such matters of public concern as immigration; group, chain and branch banking; economic conditions; unemployment insurance; communist propaganda; railroad consolidations; lobbying; and post office leases. They have kept watch on the functioning of various federal bureaus, departments and establishments; they have inspected the affairs of private citizens and corporations; and they have inquired into such other diverse matters as the conservation of wild life, the condition of the Alaskan Railroad, Indian affairs, treaties with China, campaign expenditures, animal feeds and the price of shoes.

The frequency of American legislative investigations is probably traceable to the separation of powers set up by the framers of the constitution. Their plan was so to separate the legislative, executive and judicial branches of the federal government as to prevent the abuse of power by any one branch and thus to safeguard individual liberty. But this balance of power and dispersion of responsibility proved unworkable and precipitated a struggle for supremacy between the president and Congress which has continued to this day. Congress has steadily tended to encroach upon the executive and the executive has quite as steadily sought to resist such encroachment. In the absence of ministerial responsibility or of some arrangement which would bring the administration face to face with Congress the investigative activity of congressional committees has developed in response to the need for some means of holding

the administration to a strict accountability. With the development of an elaborate administrative mechanism at Washington and the great increase of powers exercised by the executive branch this need has become more and more insistent. Governmental efficiency, the protection of private rights and the execution of legislative policy as the will of the people demanded of Congress that it devise methods of supervising the administration of the law and executive conduct.

As a legislative function investigation has several distinct advantages. It is less unwieldy and cumbersome than impeachment and less inconvenient in its consequences than budget refusal. It provides a more effective control than mere resolutions requesting information "if compatible with the public interest," and it is a substitute for a system of administrative courts to protect the citizen from the arbitrary action of subordinate officials.

The attitude of the executive toward these inquiries has varied. Occasionally presidents and cabinet members, their reputations or conduct assailed, have asked for investigations. Such requests came from Alexander Hamilton and Oliver Wolcott as secretaries of the Treasury, from Postmaster General Gideon Granger, President Monroe and Vice President Calhoun and from Daniel Webster as secretary of state and William H. Crawford as secretary of war. More often, however, the executive has vigorously resisted committee inquiries. President Jackson vehemently repelled the attempts of the Wise committee to investigate his administration in 1837; President Buchanan protested against the methods of the House in the Covode inquiry in 1860; and President Coolidge criticized the procedure of the Couzens committee in its investigation of the Internal Revenue Bureau.

Any analysis of congressional investigations must take account of their political motivation. Political interests were apparent in the investigations launched against Jackson, in the inquiries which led to the impeachment of Johnson and in the frequent scandals of the Grant and Harding administrations. Party competition for the spoils of office has been reflected in repeated investigations of the customs houses, the Government Printing Office, the Bureau of Pensions and other branches of the civil service. Party affiliation makes for party prejudice and legislative committees do not always exercise their quasi-judicial duties impartially. The

members sometimes feel obliged to advance the interests of their party even at the expense of the facts and they rationalize their actions by identifying party interest with the general welfare. There exists a strong temptation to transcend the proper limits of a public inquiry and a great disposition to enter the domain of private life. The door is open to an indefinite search after evidence; and the suspension of the usual rules of evidence and of judicial procedure has often transformed the legislative committee into a tribunal of inquisition.

But if many congressional investigations have been partisan in their inception, methods and recommendations, disinterested observers generally agree that the results have justified their use. Their value arises from the exposure which they secure and the cautionary example which they set. Corrupt and inefficient officials may be removed, forced to resign or be disciplined; court action or impeachment proceedings may follow; the Senate may exercise its control over appointments more carefully; and Congress may transfer neglected duties to another department, create new agencies or even abolish an office. Hope of gaining a partisan advantage is less open to criticism when it results in the disclosure of some abuse, while the presence of a spirited opposition usually prevents the punishment or defamation of the innocent. But the repetition of practices once exposed indicates that party policies alone are no substitute for that eternal vigilance which successful democratic government demands.

The expenses of congressional investigating committees are met either by special appropriation, which requires a bill or resolution or a provision in an appropriation bill specifying a given amount, or out of the contingent fund of the House or Senate. In the latter case the amount is not specified, authorization being left to the Committee on Accounts in the House or to the Committee to Audit and Control Contingent Expenses in the Senate; disbursements are then made by the secretary of the House or Senate upon vouchers approved by the chairman of the committee. A joint committee requires either a joint resolution or payment in equal shares from the contingent funds. Complete data concerning the cost of congressional inquiries are not available. A total of \$214,660 was expended in connection with the principal investigations conducted by the Senate from March 4, 1923, to April 16, 1924. In 1926 Senator Warren, chairman of the Senate Appropria-

tions Committee, compiled figures showing that in the preceding sixteen years the Senate had spent \$1,383,500 on various inquiries. According to the annual reports of the public printer the expense of printing hearings of Congress in the fiscal years 1922 to 1924 was \$414,614. Although these amounts seem large, one commentator, calculating that 20,000 questions are asked annually in the House of Commons at a cost of a guinea apiece, concluded that over a period of sixteen years the cost of the daily question hour in Great Britain had considerably exceeded the cost of senatorial investigations.

In addition to legislative inquiries a familiar device for investigating public administration or problems of public concern in the United States is the permanent or temporary fact finding commission, usually authorized and financed by the legislature but appointed and conducted by the executive. Federal fact finding commissions made their modern debut in the United States with the creation of the Civil Service Commission in 1883; President Roosevelt made conspicuous use of them in dealing with coal, conservation, industrial relations and other problems; and several important commissions with investigative and other functions were created during the Wilson administration, notably the Federal Trade Commission, the Federal Reserve Board, the United States Tariff Commission, the Federal Board for Vocational Education, the United States Shipping Board, the Railroad Labor Board and the Federal Power Commission. Expert commissions to investigate the tariff and other issues were promised by both presidential candidates during the campaign of 1928. In his first two years President Hoover appointed twenty-nine ad hoc commissions and committees, either upon his own initiative or by authorization of Congress, to deal with such matters as ocean mail contracts, law enforcement, agricultural marketing, child health, conservation of the public domain, wages and building construction, social trends, policies in Haiti, home building and ownership, employment, drought, timber conservation and illiteracy. A commission of congressmen and cabinet members studied methods of equalizing the burdens of war in 1931. In some quarters "government by commission" has been praised as a scientific approach to the solution of public problems; in others it has been condemned as a device for dodging issues.

Administrative investigations are financed either from direct appropriations by Congress,

as in the case of the National Commission on Law Observance and Enforcement, or entirely by private contributions, as in the case of the President's Committee on Social Trends. Some agencies, such as the National Timber Conservation Board, receive both public and private support.

In all departments of government there are agencies charged with making investigations or entrusted with administrative tasks for the performance of which investigations are essential. Large numbers of inquiries into matters of social significance are constantly functioning under governmental auspices. Congressional investigations of executive expenditures may have become less necessary since the establishment in 1921 of the office of comptroller general with supervisory and inquisitorial powers, although his influence over the departments as an agent of Congress was impaired by the Supreme Court decision in the Myers case [272 U. S. 52 (1926)].

Since 1910 temporary economy and efficiency commissions with limited funds have been established from time to time by law in many states to investigate the administrative organization and methods of the state government as a whole or of particular departments or institutions. These commissions have consisted of members of both houses of the legislature or of outside specialists or of both. The value of their work has varied. During the sessions of 1929-30 a total of 251 investigations preliminary to law-making were authorized by state legislatures. Considerable investigative work is also carried on by state governments through the research activities of industrial, railroad, taxation and other permanent commissions, banking and insurance departments and departments of education. In New York the governor is authorized at any time, either in person or by one or more persons appointed by him, to examine and investigate with enforcing process the management and affairs of any department, board, bureau or commission of the state.

Official agencies for investigating the administration of particular cities have been created in a few instances. Examples are the Boston Finance Commission (1907-09), authorized by the City Council and appointed by the mayor; the Permanent Finance Commission of Boston, established by law in 1909; the Chicago Commission on City Expenditures (1909-11) and the Efficiency Division of the Civil Service Commission of that city (1909-15); the Milwaukee Bureau of Economy and Efficiency (1910-12) and Bureau

of Municipal Research; the commissioner of accounts of New York City; and the Efficiency Department of Los Angeles (1914-17). The financial investigations of city comptrollers, as in Philadelphia, and the studies of police departments and municipal courts by local official crime commissions, as in Baltimore, also deserve mention. The legislature of New York state has several times instituted investigations into the government of New York City, the most notable being the Lexow investigation of 1895 and the Hofstadter investigation of 1931-32. Governmental inquiries in American cities, however, are infrequent, their place being taken by the unofficial investigations of bureaus of municipal research.

On the European continent the French assemblies were the first to follow the lead of the House of Commons and to assume the power to conduct investigations of the administration and to obtain information on which to base legislative policy. The commissions of the first revolutionary assemblies functioned in a way as permanent agencies of inquiry into the various branches of administration. The constitution of the Year III, however, did not mention this right of the legislature. After the Restoration there were repeated proposals for inquiries and some successful resolutions; during the July Monarchy the right of investigations was freely admitted. The right to conduct *enquêtes* has been tied up in France with parliamentary government, ministerial responsibility and the right of interpellation. Thus with the coup d'état of Louis Napoleon in 1852 all of these were abolished. Under the Third Republic the right of investigation was again successfully claimed by the legislative bodies, although there was neither constitutional nor statutory regulation of the *enquête*. *Enquêtes* are generally ordered by simple resolution, in the case of investigations of administration generally only after a commission has considered the resolution and has reported on it to the house; they can also be instituted by the adoption of an *ordre du jour motivé* to that effect at the close of the debate on an interpellation. The legislative committee cannot coopt non-parliamentary members unless authorized by the house. The right of legislative committees to require the attendance of witnesses, the production of papers and testimony under oath was not clearly established until a statute to that effect was passed in 1914. The expenses of the *enquête* are paid from the budget of the house authorizing it. Pierre lists twenty-

five investigations conducted by the Chamber of Deputies between 1832 and 1892 and five by the Senate between 1876 and 1891. Both during and since the World War the *enquête* has aided in securing more effective legislative control of the executive. It has been used by no means as frequently in France as in the United States, however, and as a method of control of administration it is distinctly less important than the interpellation.

While the legislative power of investigation was assumed in England, the United States and France as an essential corollary of the general legislative powers, the constitutions of many European countries provide specifically for this power. The earliest constitution of this type was probably that of Saxe-Weimar of 1816, which provided that the assembly of estates could set up investigating committees when it thought them desirable. Belgium made a similar provision in article 40 of the constitution of 1831. The Netherlands gave the right to the Second Chamber only in its constitution of 1848 and carefully regulated the exercise of the power in a law of 1850, but in the constitutional revision of 1887 the power was extended to the First Chamber as well. The right of legislative investigation was asserted in a number of German constitutions, including the Frankfort constitution of 1849; the Prussian constitution of 1850 reluctantly granted it in principle but left the details to subsequent legislation, which was never enacted. When legislative investigations were inevitable, special acts were passed applicable only to the particular investigation concerned; effective opposition by the government limited such investigations to four between 1850 and 1864; after the latter year the provision was practically a dead letter. The imperial constitution of 1871 contained no provision for legislative investigations; when such investigations were unavoidable they were as in Prussia provided for by special acts. Such were the acts establishing the tobacco inquiry of 1878, the stock exchange inquiries of 1892 and 1905 and the armaments inquiry of 1913. Thus although Germany had precedents for legislative investigations it had no effective provision for them until after the revolution of 1918. The Weimar constitution provides for legislative investigations under certain circumstances on the demand of one fifth of the members of the Reichstag. The constitutions of the Länder also provide for such investigations on the demand of from one fifth to one third of the members of the Landtag.

The legislative investigation in Germany is thus intended to serve in addition to its other functions as a protective weapon for minorities. By 1925 seven investigations had been authorized and in 1926 a committee was established to investigate the conditions of production and marketing in German industry; this last committee has issued a number of valuable reports. Several other European post-war constitutions established the right of investigation, but it has not played an important part in the government of the states concerned.

In the Rabkrin (Raboche-Krestyanskaya Inspektsia), or Workers' and Peasants' Inspection, the Union of Soviet Socialist Republics has a powerful organ of investigation. The Rabkrin is one of the commissariats represented in the Council of People's Commissars of the Soviet Union, the administrative agency of the Central Executive Committee, which in turn constitutes the supreme legislative and executive body of the U. S. S. R. The Rabkrin is composed of the people's commissar for Workers' and Peasants' Inspection chosen by the Central Executive Committee; three assistant chairmen, a secretary and a collegium of thirteen members subject to confirmation by the committee; four central sections for supervision of all inspection, improvement of government apparatus, bookkeeping and accounting and general administration; and information, legal and complaint departments. It has also local branches and each member republic has its own commissariat. This agency investigates all organs of government—administrative, economic and social—in order to check results and to combat red tape and bureaucracy; and it makes recommendations to the central government for simplification and increased efficiency. The Rabkrin proceeds on its own motion and also receives complaints from groups or individuals against Soviet officials or institutions. During 1930 and 1931 its Joint Complaint Bureau investigated 43,000 out of 100,000 complaints, most of which were against the *kulaki*, the administration of village soviets and misuse of office by politicians. Public and private hearings are held throughout the country and the Rabkrin has power to question the management and employees of any Soviet institution and to demand access to all books, accounts and documents necessary to its investigations. Its recommendations, which may involve removal of officials, reduction of staff, lowering of prices or reorganization of an industry, are subject to ratification by the Central Executive Committee.

An increasingly important position in the development of governmental investigations has been taken by the League of Nations and the related International Labor Organization. Through its technical organizations and permanent advisory committees, linked up with sections of the Secretariat, as well as through special ad hoc committees the League has undertaken a great many inquiries ranging over a very broad field. Characteristic of the League is the Permanent Mandates Commission, which maintains constant supervision over the carrying out of the terms of the mandates. The ad hoc commission appointed by the League to investigate the Sino-Japanese conflict in Manchuria in 1931 is reminiscent of earlier international commissions of inquiry appointed to determine disputed questions of fact in international controversies. The inquiries of the International Labor Organization have been concerned primarily with the international aspects of the problems of labor and industrial relations, largely preliminary to the drafting of recommendations or conventions for international action. Although many international investigations have functioned through direct oral examination of witnesses at the place involved in the investigation, such examination has not been based upon any power to compel testimony and the production of papers. Most international investigations have been conducted on a statistical or documentary basis rather than by means of oral hearings.

INVESTITURE CONFLICT. The subject of the investiture conflict, which raged, although not continuously, from the last quarter of the eleventh century until 1122, was the place of the secular authority in the appointment of ecclesiastical officials. While the controversy frequently tended to turn upon the right of the secular authority to give the pastoral staff and the episcopal ring, the spiritual symbols of ecclesiastical office, the important question at issue was the degree of control which the secular authority might exercise in the actual appointment. The investiture conflict may be regarded as the first phase of the sustained struggle between the spiritual and temporal powers which occupied western Europe for some 250 years after the accession of Pope Gregory VII (*q.v.*) in 1073. In the course of the investiture conflict other and more profound issues as to the relations of the two powers were raised. It is nevertheless true that it was this problem which originally brought the two powers into violent collision and made their relation one of mutual animosity. In the ninth and tenth centuries and in the first seventy years of the eleventh century the relations of the two powers were very complex and, at times, stormy. The temporal power continually wielded great influence in the ecclesiastical sphere, while the spiritual power exercised some and often considerable control over temporal affairs. This condition although partly contingent upon historical circumstances was a natural consequence of the difficulty in the practical application of an abstract principle—the Gelasian theory that each of the two great authorities was independent within its own sphere. In spite of the overlapping the actual relations of the two powers prior to the investiture conflict were on the whole sympathetic and dominated by a cooperative spirit. It is only by a consideration of the earlier conditions of episcopal appointments that the nature of the investiture conflict can be understood.

On the particular question of the appointment of bishops and abbots there was in the ninth century general agreement at least in principle. The typical view may be found in the *Epistles* (xix: 1) of Hincmar, archbishop of Reims, who

was the most outstanding churchman of northern Europe in the latter part of the century. He was clear that while having no arbitrary authority in appointing bishops the prince nevertheless had his rightful place, along with the clergy and laity of the diocese and the metropolitan and comprovincial bishops, in such appointments. In the tenth and the first part of the eleventh century the principles of Hincmar were normally recognized as just. Some writers of the time seem to insist upon the rights of the clergy and laity of the diocese to elect; others require the authority of the prince; but in the main there was little serious intention of ignoring what were regarded as the reasonable claims of both. The best evidence of this is the fact that in the tenth century writings of Gerbert, archbishop of Reims (afterward Pope Sylvester II), and in those of Peter Damian, one of the most famous representatives of the reform party of the eleventh century, it is easy to find some phrases which apparently favor the predominant place of the electors and others which seem to attribute chief weight to the prince.

The explanation of this attitude as well as the later emergence of conflict is to be found in the history of the times. The decay of the Carolingian civilization in the ninth century as a result partly of its own internal weakness, partly of new barbarian invasions, had been accompanied by a corresponding decline of the ecclesiastical life and order. Almost simultaneously with the revival of the religious life, which began in the tenth century and found its most important center in the monastery of Cluny, the political recovery of Europe was inaugurated by the reconstruction of the Holy Roman Empire by the German king Otto I. These two movements proceeded hand in hand until the middle of the eleventh century; and it was no doubt partly for this reason that even the ecclesiastical reformers tolerated the exercise of a very great authority on the part of the secular power in ecclesiastical appointments. There was another and very important reason for the development of this authority. With the growth of feudalism in the tenth century the great administrative offices of the empire had increasingly tended to become hereditary, and the emperors had come to look to the bishops with their great territorial jurisdictions as a counterbalance against the feudal nobility and as men to whom they might safely entrust great political power, provided of course that they themselves might exercise a commanding influence in appointing them.

While perhaps not trustworthy in all details the account given in Anselm's *Gesta episcoporum leodiensium* of the appointment of Wazo, one of the most illustrious of the reforming churchmen, to the bishopric of Liège in 1041 provides a good illustration of the typical and accepted method of appointing ecclesiastics in this period. After having been unanimously elected by the clergy and laity of the diocese Wazo protested that his election would displease the emperor Henry III. His objections were overruled and he was sent with a letter of the diocese and the pastoral staff to meet Henry at Ratisbon. In the deliberations of the emperor and bishops and princes of the court much opposition was manifested and it was urged that a bishop be appointed from the clergy of the royal chapel. But the active support of the archbishop of Cologne and the bishop of Würzburg finally secured the imperial consent to the choice of the diocese.

Not until the death of Emperor Henry III in 1056 did serious friction develop between the two authorities. Henry III had cooperated with the reformers in the movement against the more flagrant ecclesiastical abuses, especially the vice of simony, by which church offices were constantly bought and sold. But after Henry's death the temporal power in the empire, as in France, not only ceased to support reform but became the active cause of demoralization. Whether or not the charges brought against the administration of the empire during the minority of Henry IV and against Henry himself after he had assumed the reins of government were wholly justified, it is evident that simony was rampant both in France and in the empire.

The popes from Leo IX (1048-54) had taken energetic measures to suppress it. When Hildebrand became pope as Gregory VII in 1073 he continued their policy but gave it a new direction. Previous popes had dealt mainly with the simoniacal clergy; Gregory turned the attack against the secular authorities as being mainly responsible for the abuses. It was this which led directly to the great conflict.

The conflict first arose in France. In letters of 1073, 1074 and 1075 Gregory charged the French king with the most outrageous simony and threatened the severest penalties of the church unless he reformed. It was not until 1075, and then apparently in connection with the dispute over the appointment of the archbishop of Milan, that Gregory in a synod at Rome directly forbade Emperor Henry IV to bestow bishoprics and any layman to give investiture. The precise

terms of this decree are not known but those of the decree issued by the Roman council of 1078, at which the condemnation of lay investiture was repeated, have been preserved (Gregory VII, *Register*, VI: 5 b). The Roman council of 1080 added that any person receiving and any emperor, king or secular authority giving such investiture was excluded from the grace of St. Peter and forbidden to enter a church. As the proper mode of appointment it prescribed election by the clergy and people with the consent of the Apostolic See or the metropolitan (Gregory VII, *Register*, VII: 14 a).

While the issue was thus set, considerable ambiguity still surrounded the meaning of the prohibition. Just as the party of reform had not generally or clearly maintained that the temporal authority should have no place in appointments, but only that it should not have an arbitrary right to override the wishes of the people and clergy or to "invest" with the sacramental symbols of spiritual office and power (*Adversus simoniacos*, III: 6, by Cardinal Humbert of Silva Candida), so even Gregory VII seems in letters of 1077 and 1079 to recognize the right of the French king and of Rudolph of Swabia to some voice in episcopal appointments (*Register*, V: 11, and *Epistolae collectae*, 26).

This vagueness, only gradually clarified, is reflected in the controversial tracts which the prohibition evoked in the succeeding years. Although sometimes seeming to deny the secular authority any share in appointments the supporters of the papacy, whose position may be illustrated by the *Libellus contra invasores et symoniacos* (1097) of Cardinal Deusdedit, laid emphasis upon the abolition of the arbitrary right of the prince and upon such practical evils as the prevalence of simony and the congregation of place hunting clerics at the royal court, which according to Deusdedit arose from dependence upon the prince (prologue and cols. 1, 15). During the first phase of the controversy they avoided discussion of the secular position of ecclesiastical officers, which the protagonists of the imperial party stressed. Prominent among the latter was Wido, bishop of Ferrara, who in *De schismate Hildebrandi*, written probably in 1086, foreshadowed the later solution of the conflict by drawing a distinction between the two aspects of the bishop's office. While justifying lay investiture on the ground that the bishop's secular power and possessions must be granted by the prince, Wido admitted that his spiritual powers came through the ministry of other bishops.

In the closing years of the century the beginnings of a mediating tendency can be recognized in the position of Ivo, bishop of Chartres, a great canonist, one of the most important churchmen in France and a convinced supporter of the popes. In his *Epistola ad Hugonem* and *Epistola ad Ioscerannum* Ivo developed the view that the question of investiture should be conceived as a matter not of eternal law but of what may be called an administrative order and that the granting of the temporalities was clearly the right of the prince. Indication of a similar mediatory tendency in the opposite camp is given by the anonymous *Tractatus de investitura episcoporum*, written probably in 1109 by a protagonist of the imperial party.

Progress toward settlement was, however, interrupted in 1110 by the startling proposal of Pope Paschal II to solve the difficulty by commanding the bishops and abbots to surrender their regalia, that is, their political authority and feudal lordships and possessions, if in return the temporal power would admit the freedom of election and give up the claim to investiture. It is tempting to relate this offer to some general movement of revolt against the secularization of the church through the immense development of the wealth and political position of the bishops and great abbeys—to such a movement as seems to have been represented later in the century by Arnold of Brescia and is reflected in the writings of so pious a churchman and so devoted an adherent of the papacy as Gerhoh of Reichersberg. But unfortunately little evidence has been preserved of the considerations prompting Paschal's action. His proposals were rejected if not by the whole episcopal body at least by those German and Italian bishops who were in Rome with the pope and Emperor Henry V in 1111, and they were condemned in emphatic terms in the *De honore ecclesiae* of Placidus of Nonantula. Following the failure of this solution, Paschal, who was in the power of Emperor Henry V, was reluctantly forced by the devastation of Rome and of the surrounding country and by the imminence of schism to issue a *privilegium* providing that bishops and abbots should be freely elected with the consent of the prince and that royal investiture with the ring and staff be a prerequisite of consecration. The church as a whole, however, violently repudiated the pope's temporary submission and at a council held in the Lateran in 1112 Paschal had to rescind his *privilegium*.

In France and in England an understanding had already been reached, although the exact

process and terms of the settlement with these countries is not known. It seems clear, however, that the French king and his great vassals had gradually accepted the papal prohibition of investiture with ring and staff and without renouncing their privilege of confirmation had recognized the principle of free election. In England the controversy between Anselm and Henry I had ended during the first decade of the century with similar concessions on the part of the king, who, however, continued to exact the oath of allegiance from the bishops. But no progress toward a solution of the major conflict between papacy and empire was made until after the death of Paschal's successor, Gelasius II, in 1119. The negotiations were then resumed, at first by representatives of the French church. When these broke down they were renewed under the more authoritative influence of the German princes, who at Würzburg in 1121 expressed their determination to achieve a settlement by which the empire and the church should both retain their rights.

The result was a direct correspondence in 1122 between Pope Calixtus II and Emperor Henry V. In September, 1122, Henry and the German bishops met the papal legates at Worms, and the conflict was finally terminated by the Concordat of Worms. The concordat provided that the churches of the empire should have the right of free election and consecration and that the emperor should renounce all right to invest with the ring and staff. The papacy conceded that all elections within the German kingdom should be held in the emperor's presence and that in the case of disputed elections the emperor with the advice of the metropolitan and bishops of the province should give his assent to the wiser part (*saniori parti*) of the electors; that the bishop or abbot elect should receive the regalia from the emperor before consecration and that in those portions of the empire outside the German kingdom the bishop or abbot should receive the regalia within six months after his consecration, except in the case of those sees or abbeys belonging to the Roman church.

In recognizing both the claim of the church to freedom of election and the reasonable right of the temporal power to some voice in determining ecclesiastical appointments, which in fact held so great a place in the political life of the Middle Ages, the concordat represented substantially the acceptance of the principles of the mediating party. The concordat secured peace between the church and the empire for thirty years. When

with the accession of Frederick Barbarossa in 1152 the two authorities again became ranged against each other, different issues were at stake. There seems to be evidence of varying interpretations of the settlement even during the interim of peace, and during the reign of Frederick II in the thirteenth century the question of ecclesiastical appointments grew once more acute. But on the whole the broad principle of the concordat was fully recognized. That principle constituted the application of the dualistic theory of the relation of the two powers. The investiture conflict did not disturb the normal validity and acceptance of this theory. It is, however, true that in holding the temporal power responsible for what he conceived to be its part in spiritual corruption and in evoking every sanction that the church had ever claimed to support his case, even to the extent of excommunicating and then deposing the emperor, Gregory VII had made a practical application of his spiritual authority which involved revolutionary consequences. Thus, while the conclusion seems clear that the investiture conflict did not imply an official assertion of any theoretical authority on the part of the spiritual power in temporal affairs, it did lead to actual claims to interference with the temporal power, which although they had little practical importance in the twelfth century could furnish a precedent for the great struggles between church and state in the thirteenth and fourteenth centuries.

INVESTMENT is the act of directing the employment of funds into capital or into claims to income. In the broadest sense investment includes not only the employment of funds in the maintenance and increase of capital goods from which a present or future money income is to be derived but also the purchase of durable consumption goods from which the income stream is of a psychic rather than a pecuniary nature. In the usual business interpretation of the term, however, such goods do not represent investments. Moreover in business terminology investment is regarded from an individual point of view rather than from the point of view of the community; that is, it is regarded as the transformation of current income into claims to future income rather than as a transfer of savings to those who can make the most productive use of them with a resulting increase in the capital and income producing power of the community. During 1918, for instance, the investments of the American people amounted to about \$22,000,000,000, yet the net loss in the physical capital of the country through war activities amounted to \$2,000,000,000. While some capital was destroyed and the social income stream lowered, certain individuals went through a process of investing funds and held higher claims to future income in the form of government promises to pay.

The maximum available for investment is the total savings, or the amount by which money income exceeds money expenditure on current consumption. Saving is dependent upon a large number of factors, among the most important of which are the natural resources of a country, its efficiency of labor, its stability of government, its distribution of wealth, the thrift, foresight and education of its people, and the development of institutions encouraging the accumulation of savings and facilitating their gainful employment. These factors affect the amount of saving because they influence the ability and willingness of a people to save. Thus the larger the natural resources of a country and the greater the efficiency of its labor, the larger is the excess of income over the amount required for subsistence and the greater is the ability to save

for the country as a whole. For a single individual the ability to save is a function of the size of his income relative to the subsistence minimum; hence, other things being equal, the more unequal the distribution of wealth in a country, the greater its ability to save. Willingness to save depends very largely upon the established mores. For people with very large incomes willingness to save is a factor of less importance, as their saving is largely an automatic accumulation of unspent income. Even a certain amount of saving by the mass of the population may not be the result of a deliberate decision, particularly in countries with a strong commercial banking system. Through the creation of new purchasing power, which is transferred in the form of credit to producers, the banking system increases the ability of the producers to draw upon the resources of the community, reducing ipso facto purchasing power in the hands of consumers. In highly developed industrial countries corporate savings, or the amount of corporate net earnings which are not distributed to the stockholders in the form of cash dividends, form a significant part of total savings. The larger the net income of a corporation relative to the outstanding capital stock and the more promising the opportunities for expansion in the business in which the corporation is engaged or in related lines of business, the more likely is the corporation to retain a part of its net earnings. Even in a capitalist society saving may be undertaken also by the government when it employs the proceeds of taxation for public works and other productive purposes; whether the total savings of the country are increased thereby depends of course upon the uses to which the individuals would have turned that part of their income which is appropriated by the government through taxation. Apart from other considerations the total amount of savings varies with changes in general business conditions. Corporate savings depend upon the movement of business activity; they are largest in years of prosperity and smallest in years of depression. Individual savings, which depend on the size of current income, likewise vary although less widely than do corporate savings. Estimates have placed the amount of savings for the United States in the year 1924, a fairly representative year, at about one sixth of the national income and for the United Kingdom at about one eighth of its national income.

Saving and investment are not coterminous. At all times, at some to a greater extent than at

others, a certain amount of saving takes place which does not result in immediate investment. Savings may be hoarded because investment opportunities are scarce or do not offer sufficient security, as in a period of financial uncertainty. Hoarded savings are in no sense investments, since the term investment implies the employment of funds in a manner which gives to the investor a claim to income either in the present or in the future. Savings which are not hoarded may be employed in a manner which is essentially different from genuine investment; they may be used for speculation—for the acquisition of goods which are expected to appreciate and which represent from the point of view of the purchaser an anticipated increase in capital value rather than a more or less permanent claim to future income.

There are certain general considerations which investors of all types take more or less into account: yield and appreciation possibilities, the ability readily to dispose of the investment (marketability) and safety. These are to a certain extent mutually incompatible—a high degree of safety, for instance, goes generally with a low yield—and the investor will therefore tend to emphasize one of these desiderata at the expense of the others. Even where investments are diversified the composition of the investment portfolio will reflect the bias of the investor with reference to each of these investment principles.

Apart from the purposes which he has in view the individual's choice of investments will be affected by the size of his income and his knowledge of investments. An individual with small income who desires to save for emergency and for competency in old age may find it difficult to obtain the diversification in investments which he desires; consequently his savings may be entrusted to a savings bank in the form of deposits or to an insurance company in the form of premium payments. Other individuals with greater ability to save may place a portion of their savings with banks and insurance companies and invest the rest in stocks, bonds and mortgages.

Where the individual's knowledge of investment opportunities is limited and his capital large enough to warrant the cost, he may use the services of investment counsel, which will help him to obtain such diversification of investment as is best suited to his needs; or he may entrust his savings to financial institutions which make it their business to invest the savings

of others in such a manner as they deem advisable, subject to certain restrictions imposed by public authority. The individual, however, will still have to choose among the various types of investing institutions. These include among others savings banks, which receive savings too small in amount to obtain the safety made possible by diversification; trust companies, which handle in a fiduciary capacity the funds and estates of individuals; and investment trusts, reaching that part of the investing public which desires diversification, higher yields than might be obtained elsewhere and opportunity for capital appreciation. Other investing institutions are building and loan associations and to a certain extent life insurance companies.

From the social point of view an act of investment results in the addition to the capital equipment of the country, unless the investment is made abroad. In primitive societies capital equipment is maintained and increased directly—by turning labor that could be spared from the production of consumer goods to the production of equipment. With the development of the money economy the process of capital formation becomes more complicated: the funds for the purchase of capital goods produced by specialized industries are obtained from individual savers. Before the industrial revolution investor ownership took the form of a direct ownership of productive wealth, a form which still predominates in the less industrialized countries. With progressing industrialization this older form of direct ownership has been increasingly displaced by indirect ownership through stocks, bonds and other securities. The value of outstanding securities in the United States in recent years may roughly be estimated at one third to one half of the national wealth; in England it was estimated at 60 percent of the national wealth for 1918.

In an individualistic society the investor is left more or less free to decide which of the various enterprises bidding for his funds are to increase their power of commanding capital goods. The correctness of his decision will be reflected in the future market value of his investment; thus if the industry in which he invested is overexpanded relative to the demand for its product, his investment will depreciate. Under these conditions a certain amount of overinvestment in some industries and capital shortage in others cannot be avoided. In a planned society, where the flow of savings into various

industries is regulated by a central authority, much of this maldistribution could presumably be eliminated except for some radical and unexpected shifts in consumer demand.

In a developed capitalist society the judgment of the investor, whether he acts directly or through an investing institution, is directed by the machinery of the organized investment market, the two important constituents of which are the investment bank and the stock exchange. The investment banker acts as a middleman between those who require funds and those who have a supply of funds to offer. His profit is obtained from the margin between the price at which he underwrites the issue and the price at which he disposes of it to the public. Large corporations, to the extent that they seek capital not furnished through reinvestment of earnings, as well as states and municipalities normally satisfy their capital requirements through the services of the investment banker. The financing of hotels, office buildings and apartment houses is frequently done through the investment banker by the issuance of bonds secured by a mortgage on the property. Capital for the purchase and erection of homes, in so far as it is not obtained from building and loan associations, is raised by special companies which deposit mortgages on the property with trustees and issue bonds against this collateral; mortgage companies have developed in the United States only in recent years. Many financing programs, however, are not arranged through investment banking institutions. The demands of a national government are generally handled through the agency of a central bank, which in turn enlists the cooperation of investment houses. A few of the larger corporations, particularly certain public utility companies which have a wide and direct contact with the public, do a part of their financing without the mediation of the investment banker. This is likewise true of concerns whose capital requirements are relatively small and in which investors in general have little interest. In some European countries the functions of investment banker for industry are assumed by ordinary banks directly or through a subsidiary finance company, and loans on mortgages for the construction of homes and for agricultural uses are raised through mortgage banks owned by the public authority or by a cooperative association.

Just as the raising of capital funds is facilitated by the investment banker, so the transfer of capital is effected by security brokers who act

as intermediaries between buyers and sellers of securities. The purchase and sale of securities through brokers is facilitated by stock exchanges whose members enjoy the privilege of transacting business on the exchange. Only securities listed by the stock exchange committee can be traded on the exchange; securities with restricted markets are not approved for listing and are dealt in "over the counter" trading by specialized bond houses and similar institutions. Although the mere listing of a security does not necessarily assure it a ready market, since some securities are not actively traded, nevertheless a security which can be sold on the exchange is as a rule more marketable than an unlisted security and is for that reason preferable from the investor's point of view. Thus by improving the marketability of securities the stock exchange facilitates the raising of capital. An extremely important consequence of marketability due to the continuous functioning of stock exchanges is that a part of the investment needs of the country can be satisfied by the employment of commercial bank funds, which flow into the investment market as the result of loans to investment banks and brokers and as the result of direct investments in stock exchange securities by commercial banks.

One of the most important classes of securities for which market facilities are relatively inadequate is real estate mortgages. Individual real estate mortgages differ fundamentally from mortgage bonds in that the holder of the individual mortgage proceeds alone in the execution of his rights in case of default, while the holder of a mortgage bond proceeds through the intermediation of a trustee. The absence of a centralized market for real estate mortgages has been due to the nature of these mortgages. They often cover small pieces of local property, the value of which cannot readily be determined by scattered investors, and they may be of inconvenient denominations; moreover they require a considerable amount of attention with respect to maintenance of tax payments on the property, the regular payment of insurance and other details. It is to make these mortgages a more desirable investment that mortgage companies have developed which deposit individual mortgages with trustees and issue real estate mortgage bonds against this collateral.

Investments in stocks, bonds and mortgages are investments in the permanent capital of a country; from the point of view of the community the process of liquidating these investments

is normally a very slow one: the value invested in capital goods can be recovered only bit by bit from the sale of the commodities in the production of which they are employed. But the individual investor who wishes to recover his principal does not need to await the more or less distant maturity date in the case of contractual obligations, such as mortgages and bonds, or the liquidation of the concern in which his investment has been placed; he may sell his securities if there is a market for them and thus transfer his investment to others. The sale of securities at the price which was paid for them is, however, uncertain.

Investors who are particularly desirous of liquidity usually find that a portion of their funds may advantageously be placed in short term investments, such as commercial paper, trade and bank acceptances and demand or time loans against stock exchange collateral. These represent short term loans, usually for working capital purposes in contrast to fixed capital purposes, which are in many cases self-liquidating. Commercial banks, whose obligations are in the form of deposits payable on demand or at short notice, find it desirable to employ part of their funds in such forms. In the marketing of these loans certain specialized businesses have developed, such as acceptance and commercial paper houses.

With the increasing complexity of the investment market the apportionment of savings between industries has become more and more dependent upon the network of financial institutions. Investment banks are in a position to accept or reject applications for the flotation of securities which are brought to their attention. Commercial banks determine whether deposits left with them shall be loaned to particular enterprises. These institutions act as intermediaries between those who need capital and those who have capital to offer; but they are organized as businesses for a profit which is regulated by the margin between the price at which they furnish capital and that at which they obtain it. They will therefore direct savings not into industries which are in the greatest need of capital from the point of view of the community but into those industries which allow them the largest profit margin. The latter of course depends also on the price at which securities can be sold to investors. Assuming that the investors are well advised, they will adjust the price which they pay to the profit prospects of the industry in question; and these are determined

by the demand of consumers for the goods and services of the industry. Ultimately therefore the apportionment of savings among industries is regulated by the distribution of demand for their products; by and large investments will tend to be placed in capital goods which are calculated to produce commodities demanded by consumers. But the immediate and direct control of savings is in the hands of the institutions constituting the framework of the investment market, while the part played by consumers is an indirect one and subject to many qualifications.

The fact that an overwhelming share of the new capital for industry is supplied not directly by the investors but through the investment market means also that the investor is removed from direct control over the use to which his investment is put. A person who employs his savings in a small local enterprise, even if it is only in the form of a long term loan, retains a great deal of influence over the policy of the firm; but if he invests them in securities he acquires nothing more than a potential claim to income. Control of the physical objects on which the investor's money has been spent and of the business opportunities arising from the combination of the physical properties into a going concern is vested proximately in the management. Where the management is not a self-perpetuating group subject to no real control, as it is sometimes in large corporations whose stock is widely distributed, the control over it is likely to be in the hands of a small group of people who own only a very minor part of the total investment. For investor control there is substituted sometimes continuous control by the investment banker, one of the functions of which is to assure sound management for the benefit of the investor; this purpose, however, is often submerged by other aims which the investment banker is likely to regard as important, such as the exclusive handling of the financing operations of the concern and the effective coordination of the activities of the concern with those of others similarly controlled by the banker or by the group of financial capitalists with which he is affiliated.

The obtrusion of the investment banking machinery between the investor and industry tends also to accentuate the cyclical fluctuations in the flow of savings into investment channels. When the market for securities is good, the investment banker generally attempts to take advantage of this fact by encouraging industrial

concerns to a generous issue of securities; in periods of depression, on the other hand, the pessimism prevailing in the investment market discourages borrowing even for legitimate expansion. Adequate control over the flow of savings into investment channels might go far toward moderating the alternate periods of extreme prosperity and depression so characteristic of modern capitalist economy. Central banks in all countries have been granted broad powers designed to control money rates and the volume of credit, with the ultimate purpose of moderating the course of industry and of commodity prices. If through this means price and business stabilization could partially be achieved, investment losses through changes in the purchasing power of money might be reduced.

In the formative period of capitalist economy during the late eighteenth and the early nineteenth century investment institutions were subject to little regulation by the state. Under the influence of the philosophy of natural liberty and of natural rights it was assumed that the maximum economic welfare of the group is attained through the free and unhindered play of individual self-interest. As wealth and income increased, industrial organization assumed a predominantly corporate form; the investment market became more complex and the attainment of adequate knowledge by the individual of the industries and companies in which his savings were placed became increasingly difficult. His losses, for which poor judgment was primarily responsible, were increased by mismanagement and fraud on the part of certain financial institutions. Consequently the efficacy of the principle of *laissez faire* as applied to the investment market was questioned and, while the fundamental concepts of the earlier system remained, regulatory measures designed to protect the individual were enacted. Commercial banking became subject to regulation early in the nineteenth century. Insurance companies, building and loan associations and savings banks have similarly come under state supervision. Laws have been enacted to prevent the sale of fraudulent securities, and the issue of securities has been controlled through the regulation of corporate business. With the organization of the investment market its representative organs have imposed a considerable amount of control on the activities of the individual investment banking institutions. So vitally does investment affect the individual, state and world economy that there are tendencies for the whole field to be

subjected to greater scrutiny and regulation than have heretofore prevailed. The relation of foreign investment to tariffs, to trade balances and to the international flow of gold has received increasing attention since the World War, particularly during the depression beginning in 1929. Some form of public control over security issues to prevent overinvestment in fixed capital by private enterprises has been strongly urged in recent years, but so far such control has been fully exercised only during the World War and in the post-war period in Russia, where the entire industrial system operates according to plans laid down by the government. Control by public authority over the investment in and the import of capital from foreign countries has been more common, but it has been exercised with a view more to the political consequences of capital migration than to the economic effects of over- or underinvestment.

INVESTMENT BANKING. Banking, or the business of receiving and lending the funds of the community, is described as commercial banking when it consists of receiving demand and short term deposits and making short term loans and as investment banking when it involves mainly originating and distributing long term securities, such as bonds and stocks. The basic functional difference between commercial and investment banking is the time factor: commercial banks facilitate the transfer of short term funds, whereas investment banks deal in long term capital. Investment banking therefore is largely utilized to finance the creation and use of durable capital goods, while the purpose of commercial loans properly so called is usually to finance a single business operation. Investment and commercial banking, however, are not as clearly separated in practise as they may be made to appear in a theoretical analysis: commercial banks in many countries play an important role in supplying long term loans, while investment banking houses not infrequently sup-

ply short term advances to governments and corporations, with or without public offering of the evidences of short term indebtedness.

Investment banking has played a vital role in modern economic life. One of the most typical characteristics of the present industrial order is the large scale enterprise financed through the aggregation of funds of numerous individual investors. The investment banking mechanism furnishes the channel through which funds are combined and directed to users who hold out prospects of an attractive return and protection for the original investment. While those who can utilize long term funds profitably might and at times do appeal for them directly to the investing public, in practise this is frequently a crude and wasteful process as compared with the specialization of this function in the hands of organizations which have won the confidence of the investing public and which stand ready to appraise expertly the credit of those who apply for such funds. By handling many security issues the investment banker can spread his expenses over a large volume of business and so cut down to moderate proportions the cost of investigating and distributing each offering.

The growth of investment banking coincides roughly with the evolution of modern capitalism. More specifically, modern investment banking dates from the nineteenth century and is the result of certain economic and political developments within capitalism. One of them is the rise of the modern state. Governments have been the earliest and most persistent borrowers from investment bankers, and the investment banking mechanism was originally created in most countries to help finance the government. In the nineteenth century the number of strong and stable governments which could be regarded as preferred risks increased; at the same time loans to governments became safer because they ceased to borrow for war purposes primarily and developed instead a tendency to borrow heavily for productive purposes, such as public works. Even more important for the later growth of investment banking was the development of large scale corporate industry. Because the investment banker is typically a merchandiser of securities, his task is greatly lightened if he can offer his clients issues of large and well known corporations. Such corporations by tending to adopt financial policies which make for more continuous financial strength create for their bonds and stocks a favorable status as investment media. Allied with the growth of corporate busi-

ness was the development of the export of capital. As nations became industrialized and turned to foreign markets as outlets for surplus production they had to extend long term credits to less well developed regions in need of equipment. The export of capital assumed major proportions in several countries during the nineteenth century and added the financing of governments and industries abroad to the other activities of investment banking organizations.

The mobilization of capital through investment banking media was facilitated during the nineteenth century by the rise of institutional investors and investing institutions, which furnished a large and certain market for securities at all times except in periods of major deflation. Life insurance companies built up reserves aggregating many billions of dollars invested largely in real estate mortgages and securities; other insurance carriers also accumulated in the course of time large reserves which had to be invested. Commercial banks properly so called devoted part of their assets to the purchase of securities. At the same time eleemosynary institutions and general business corporations became buyers of securities in vast amounts. There was also a great increase in the number of individual investors. The evolution of the money economy early created a special class in the community which received money incomes substantially in excess of expenditures, furnishing a surplus available for investment; the proportion of the population in receipt of such surplus money incomes has steadily increased in economically advanced countries. In the more industrialized nations participation of the mass of the population in the investment banking process was encouraged by the creation and spread of investing institutions, such as savings banks, trust companies and investment trusts, which act as agencies of cooperative investment for numerous individual savers.

In its more primitive form banking was concerned often with investment as well as commercial operations. Banking in antiquity, as judged by the fragmentary evidence available at present, appears to have been largely commercial in character; but allowance must be made for the fact that governments sought long term credits and that certain industries, such as shipping, required even at that time outside long term capital. During the Middle Ages banking was practically unknown as a separate business, but whatever banking was carried on was largely of the investment type. Thus the Bank

of Venice, known as the first public bank, was primarily a transfer office for public debt and was created through a forced loan levied on the wealthy citizens of the republic. The Lombard bankers combined extensive trading operations with the grant of long term loans to lay and clerical rulers. The Bank of England itself was founded in 1694 as a device for raising a long term loan for the government; it obtained the note issue and banking privilege in return for an advance at 8 percent of £1,200,000 to the government of William III.

The tendency of banking institutions to specialize along either commercial or investment lines became manifest first in Great Britain. The reasons for it are largely historic. Since London developed as a center of international trade before it became the financial capital of a great industrial nation, its banks early concerned themselves with the financing of trade. British industry, which was the first to experience the rapid transformation and expansion known as the industrial revolution, has been built up from small units and financed largely out of its own profits or by local investors rather than through large public issues of securities. The earliest and perhaps the most important type of investment banking institution in England were the merchant bankers or acceptance houses. These houses, originally engaged in trade, gradually built up reputations for financial strength which made their credit generally acceptable; their major interest shifted then from trading in goods to the acceptance of bills drawn on them by English and foreign merchants. In the course of time foreign governments also turned to them as an easy means for tapping the London capital market, with the result that they became important also in foreign security financing. For a time some merchant bankers, such as Overend, Gurney and Company, sought short term deposits, allowing a liberal rate of interest in order to attract funds for long term investment abroad; but the collapse of this famous Quaker firm in 1866 precipitated a major panic in London and tended to establish in Great Britain more firmly than ever the desirability of institutional specialization. Merchant bankers have refrained as a rule from financing home industry. The same is true in the main of houses of issue, which are large investment banks specializing primarily in the origination of new issues. The long term financing of domestic industry, where the organized investment market is drawn upon, is done through

finance and investment companies or through promoting groups created for the flotation of specific issues. Some issues are undertaken also by ad hoc groups of investment trusts, finance companies, insurance companies and large individual investors, the purpose of which is to benefit their participants to the extent of underwriting costs and profits. The distribution of securities to the ultimate investor is handled mainly by brokers working for a commission, although in recent years joint stock banks, which otherwise specialize narrowly in the commercial banking business, have undertaken to execute security orders for their clients.

On the continent of Europe the tendency has been for both commercial and investment banking to be carried on by the same institution. This combination of functions is to be explained largely by the comparative lateness of the industrial revolution in these countries and by the absence of a substantial body of individual local investors ready to finance home enterprise. The relatively large units necessary to take advantage of modern industrial methods could be founded in these countries only with the aid of banks which provided long term as well as working capital and often took an active role in initiating, planning and promoting enterprises. This is clearly illustrated in the history of German industrial development after the creation of the empire. The large German banks promoted the establishment of new enterprises, financed the expansion of old ones through short term loans funded after a while into long term obligations and on the whole tended to dominate large scale industry through the retention of substantial blocks of securities and through controlling access to the capital market. Investment banking in all continental countries is carried on more or less on the German model, the only important exception being France, where banks are more specialized. The large credit banks in France confine themselves on the whole to distribution of fixed interest securities through their numerous branch offices, while the *banques d'affaires* act as full fledged investment banks originating new issues, distributing them to large investors and carrying substantial blocks of securities in an attempt to retain control and stabilize the market. Both types of institutions tended until the World War to neglect home industry, with the exception of railroads.

Of less importance than the general banks in the evolution of investment banking on the con-

tinents have been two types of organizations—private banks and finance companies—which have engaged primarily in investment banking and at times carried on a competitive struggle for supremacy. Many of the private banks, resembling the English merchant bankers, were family enterprises which attained to prominence in the eighteenth century, some tracing their history back to the Middle Ages. One of them, the house of Rothschild, assumed during the nineteenth century a dominant position in the more important money centers of Europe. Private bankers constituted the financial aristocracy of their countries and exercised an influence in business and politics entirely out of proportion to the amount of capital under their control. Finance companies were launched by public subscription, especially during periods of prosperity, to enrich their stockholders by the fabulous profits that were supposed to be reaped by investment bankers. One of the earliest and certainly the most spectacular of the continental finance companies was the *Société Générale du Crédit Mobilier* incorporated in 1852 in France. Its organization was encouraged by Napoleon III as a balance to the power of the Rothschilds, who had been very intimate with his predecessors on the French throne. Its prime purpose was to furnish long term credits for large scale business by selling its obligations and shares to numerous small investors. It engaged in industrial promotion on its own initiative and sought to dominate the market for new issues by bidding vigorously for prospective new offerings, by purchasing outstanding securities in the open market and by making a large volume of security loans. The *Crédit Mobilier* eventually got into difficulties and was reorganized as a commercial bank of deposit and discount, but its methods were copied by many German and French banks and its influence is believed to have been substantial in shaping the course of development of continental investment banking. The experience of the *Crédit Mobilier* is typical of the history of later finance companies; organized during security market booms and depending upon public security issues for their funds, they have been burdened with a frozen portfolio in the subsequent period of deflation. General finance companies must be distinguished from companies created by groups of bankers, with or without the participation of industrialists, to facilitate the financing of an important industry which has been brought under unified control or attempts organized expansion into foreign fields.

Finance companies for specific industries are quite common in the smaller continental countries and are found also in England. In Germany the finance company is generally a subsidiary of one of the large banks or of an important industrial combination.

In the United States investment banking was much slower in developing than commercial banking. Incorporated banks which began to grow rapidly at the end of the eighteenth century were at first restricted to commercial activities; and both the first and the second Bank of the United States were by their charters limited to dealing in bills of exchange and bullion. The assumption of the national and state debts by the federal government after the adoption of the constitution created a temporary flurry of interest in securities; the beginnings of brokerage organizations in New York and Philadelphia are traced to this period. Capital to finance a few large enterprises and the Louisiana Purchase was obtained largely from England and Holland, the two most important capital markets at the time; also the internal improvements and the westward expansion which followed the War of 1812 were based on large imports of capital from abroad, chiefly Great Britain. As the capital import movement grew, a special mechanism was gradually evolved to handle it. Some Americans, like George Peabody, a Yankee dry goods merchant, opened houses in London to bring American securities to British investors. The second Bank of the United States, after being rechartered in 1836 as the United States Bank of Pennsylvania, opened a London agency and sought to popularize American securities there. Conversely British houses, like the Barings, built up American connections of their own and even the Rothschilds after long hesitation sent August Belmont as their personal representative to the United States. A few domestic investment banking houses served the home market exclusively. Many of the commercial banks bought bonds at the time or made loans on them freely, and in the period of "wildcat banking" the distinction between commercial and investment banking became very tenuous.

The collapse of the United States Bank of Pennsylvania and defaults on state securities after 1841 cut off for a time the supply of capital from abroad and stimulated the growth of a domestic capital market, which prior to that time consisted of a few wealthy traders and shipowners in New York and Philadelphia. Because of disastrous experiences with wildcat

banks there was a general tendency to draw a sharper distinction than heretofore between commercial and investment banking, both in law and in practise. As a result security houses combining issue and brokerage functions gradually came to the fore, especially in connection with the railroad financing of the period. In the years from 1840 to 1860 such houses as E. W. Clark and Company of Philadelphia, which helped finance the Mexican War, and Drew, Robinson and Company of New York, which included Daniel Drew and aided in the financing of the Erie Railroad, were organized.

During the Civil War the development of investment banking was further stimulated by the exclusive reliance upon domestic financing forced upon the union government by its lack of popularity in Great Britain. Funds were obtained through a syndicate of banking houses under the leadership of Jay Cooke and Company, the first such operation carried out in the United States; and the sale of a billion dollars of government bonds to a vast number of individual investors was successfully accomplished through the use of salesmen and advertising.

After the war the investment banking mechanism developed during the conflict was shifted to the sale of railroad mortgage bond issues, stimulating the overdevelopment in this field which led directly to the panic of 1873. While Jay Cooke and a number of other houses that had turned to railway financing collapsed during the panic, others continued active in the retail distribution of securities; and in the following twenty years the size and strength of the security selling organization enjoyed further growth. Many new firms were started, while several mercantile and trading organizations shifted to investment banking in response to the attraction of larger profits, thus repeating the history of the English merchant bankers. The house of J. and W. Seligman, for example, evolved from a mercantile to an investment banking status during this period, and Lehman Brothers changed from a cotton to a security house. In addition there was a marked tendency for many investment houses throughout the country to shift their major activity to New York as the financial center of the nation.

International bankers, whose relative importance had waned during the Civil War and post-bellum days, came to the fore again in the 1890's when a wave of railway receiverships engulfed about one fourth of the railway mileage of the country and the gold standard was endangered

by the monetary policies of the federal government. Houses like J. P. Morgan and Company with excellent English and French connections, Kuhn, Loeb and Company and August Belmont and Company with strong German and Austrian affiliations, took the lead in the reorganization of bankrupt railroads and the rehabilitation of government finances.

In order to make their work of railroad construction effective the bankers had to take a keen interest in management. Prior to this time American investment bankers, following the English tradition, concerned themselves mainly with the sale of securities; they assumed only a minor role in the enterprises which they financed leaving the active heads of the business free to determine its policies. It was principally due to this fact that American enterprise retained control in a large number of concerns financed largely with capital imported from abroad. But the international banking houses which reorganized the network of bankrupt railroads were too jealous of their reputation and too keenly aware of the dangers involved to leave management in the old hands. Not only did they take prominent places on boards of directors but they also merged properties, bought control of competing railroad lines and formed holding companies or voting trusts which tied up control of individual lines for a number of years.

The period of prosperity which followed the election of McKinley in 1896 made the railway reorganizations and combinations of the preceding years extraordinarily successful. The great banking houses, their prestige raised and their wealth multiplied by the successful railway reorganizations, proceeded to apply the same methods to other industries, thus initiating the era of industrial mergers which followed the turn of the century. Frequently they took the lead in organizing combinations—the United States Steel Corporation, for example, was directly promoted by J. P. Morgan and Company—and in other cases, where industrialists or promoters initiated the combine, the bankers took over control when their financial aid or managerial ability was sought.

While in the time of Jay Cooke the house with the most salesmen and the largest number of clients was in the lead, during the period of reorganization and combination stress was laid upon origination rather than distribution power. In the following decades the actual work of domestic security distribution fell increasingly to

relatively small organizations scattered all over the country; and the big international banking houses, whose prestige stood high with institutional investors and retail dealers at home as well as with security distributors abroad, held a dominating position in the financial markets. At the same time a number of financial institutions other than investment banks were drawn into the security business. During the great speculative boom trust companies, which had for some time exercised general banking powers without specific regulation in New York and other states, became active also in the security markets. The large life insurance companies, in possession of huge reserves and closely affiliated with investment bankers, participated freely in underwriting the numerous issues of securities floated in connection with large merger and expansion programs. Commercial banks, although limited by law in their powers of engaging directly in the investment banking business, purchased bonds freely and greatly increased their security loans during this period.

The panic of 1907 was followed by considerable readjustment. The Hughes investigation in New York state caused the removal of life insurance companies from the security underwriting business, although they continued as the largest single group of security buyers. The failure of the Knickerbocker Trust Company in New York City brought about laws for the regulation of trust companies, but these did not interfere directly with their security purchasing or underwriting activities. While greater specialization of function among financial institutions was thus enforced, commercial bankers made use of security affiliates incorporated under state law in order to enter freely into investment banking operations. To preserve identity of ownership between the bank and the security company the stock of the latter was deposited in trust for the benefit of bank stockholders and it was provided that bank stock could not be sold without the transfer of stock ownership in the security affiliate. The First National Bank of New York organized the First Security Company in 1908, the National City Company followed in 1911 and in the ensuing years commercial banks in a number of cities followed suit.

The World War and post-war periods witnessed a spectacular expansion of the investment banking mechanism in the United States. The unprecedented increase in the number of individual security holders during the war, a result of the intensive Liberty bond campaign, paved

the way for the enormous sale of corporate and foreign securities after the war, a course which was facilitated by the prosperity of the 1920's. The avidity of the public for new investment and later for speculative issues exceeded all bounds, and the rapid expansion of bank investments and security loans to individuals and brokers created purchasing power with which to pay for the new flotations. Because of their strategic position the security affiliates of banks played during this period an increasingly important role in the origination and even more in the retail distribution of securities. So broad did the security market become and so plentiful were the available foreign bond issues, investment trust securities and all kinds of industrial flotations that numerous new or formerly obscure organizations rose to prominence and competed vigorously with the older and well established houses. The latter were compelled in many cases to change their methods to keep pace with these less conservative and often remarkably effective rivals. Even where the older houses became less active, however, the fact that they still played a prominent role in the management of many leading enterprises through interlocking directorates and substantial stockholding enabled them to maintain a position of influence. In addition a number of organizations other than investment banks became once more engaged in the security business. Investment trusts, particularly those affiliated with investment houses, participated in underwriting activities. In the public utility field some holding companies took a prominent part in the financing of their subsidiaries, organizations like the Electric Bond and Share Company and Stone and Webster, Inc., combining management and investment banking functions. The stock market panic of 1929 and its aftermath caused considerable mortality among the newer organizations and enhanced the prestige of a number of the older houses; it also led to agitation for a return to the earlier basis of institutional specialization, particularly through a reduction in the activity of commercial banks in the security markets.

Outside the United States, to which Canada is closely linked with respect to investment operations, and the European countries the development of investment banking has been retarded by the absence of a large class of individual investors. Thus in Japan despite the attempts made by the government to foster investment in home securities by people of small means a compila-

tion made in 1928, a year of comparatively active new financing, showed that 92 percent of the new issues was sold to banking, trust and insurance companies and only 8 percent was taken up by individual investors. Such conditions do not warrant the creation of a specialized investment service; whatever investment financing is done locally must be consummated by general banks.

The investment banking mechanism of each country and period has been strongly influenced by the type of borrower seeking funds in its capital market. In Great Britain, for example, foreign government financing called for a small group of strong houses under whose auspices the rank and file of investors could be successfully appealed to. With the coming of the railway era it became necessary to evolve new channels for raising the capital needed and the great railroad building boom of 1844-47 brought into prominence a group of contracting and financing houses that subsequently played an important role in London investment banking. Again, new types of institutions became important in several European countries immediately after the World War when, through the cooperation of banks with the government, organizations were created to promote the expansion of foreign trade by providing intermediate and long term credits. An interesting outgrowth of industrial rationalization in the subsequent period was the holding, promoting and financial enterprise of Kreuger and Toll, based in the first instance on the successful monopolistic organization of the Swedish match industry. It made large loans to governments in return for match monopoly concessions and obtained funds by selling its own securities in the richer capital markets of the world. The taint of fraud in its management as well as the world wide depression brought on its complete collapse in 1932.

Investment banking practise is even less standardized than investment banking organization. The manner in which security issues are handled varies not only from country to country but also within the same country, depending upon the size of the issue, the investment or speculative character of the security and its other relevant characteristics. Generally, however, the course of each new issue may be said to consist of three successive stages—investigation and negotiation, purchase, and distribution.

New security offerings come to the investment banking house in a variety of ways. The very large corporations maintain continuous financial

and personal relations with a banking house, such relations being often based on interlocking directorates. Buying representatives of the banking house and independent agents and negotiators also play an important role. Smaller houses usually obtain securities for distribution by joining syndicates initiated by the larger organizations. Many issues of a less seasoned character are brought to an investment banking house by direct application on the part of corporations, while in the case of municipal issues and railway equipment trust certificates competitive bids are sought because of the high degree of standardization found in this field. However the new offering may be brought to the attention of the investment bank, its statistical or buying department will make an investigation. Often an option will be taken on the issue for a period of time while thoroughgoing accounting, engineering and financial surveys are made, at times with the aid of outside specialists. If the investigation leads to a favorable result a purchase agreement is drawn up describing the issue and the terms on which it is to be taken over.

Because of the magnitude of possible losses investment bankers prefer to share risks, even those they assume only for a short time. Accordingly it is customary for issues to be purchased, either in the first instance or immediately after acquisition by the originating house, by a banking group. In the case of large issues two or three such groups may be formed in rapid succession, additional houses being brought in at each stage to spread the risk further and to interest additional organizations in the eventual distribution. When an issue is purchased outright by the investment banker it is said to be underwritten; the term, however, is also used in a narrower sense when bankers underwrite the sale of an issue offered directly by the corporation to its existing shareholders. Because of the legal preemptive right of shareholders in most corporations to subscribe to additional common stock issues such offerings of established companies are generally made first to their own shareholders, with the underwriting bankers standing ready to take over the unsold portion.

Since sudden changes in financial conditions may make new security issues unsalable after their purchase by investment bankers, a large measure of risk is incurred by them in comparison with the profits that can be made on any one issue and the capital that must be embarked

in the business. It is customary therefore for the original purchase group to form distribution syndicates to take over and sell the issue to investors in the shortest time possible. Such syndicates bring to bear the joint efforts of their sales forces and established connections with numerous small dealers to push the sale of each issue; thus they are able to reduce the risk incurred by shortening the time needed for selling and also to obtain a more widespread and hence more effective distribution. The original purchase or banking group may at times use selling groups instead of distribution syndicates; these do not underwrite the sale of the issue but merely obtain a "dealer's discount" from the offering price to the public if they accomplish sales to their clients.

The gross income of investment banking houses is obtained primarily from the spread between the purchase and sales prices of new issues. Among the important supplementary sources of revenue are the acquisition of bonus shares and blocks of securities at low prices in connection with new issues or promotions and the exercise of fiscal agency functions for governments and corporations for whom financing is carried out. Expenses arise chiefly from salesmen's commissions, advertising and the overhead cost of running the organization. A prominent item of expense is the cost of large loans from commercial banks, arranged by syndicate groups or by individual houses and protected by security collateral. Investment banking organizations must resort to such loans, because their capital usually constitutes but a small percentage of the total commitments they undertake. The slowing down of the process of security distribution, especially in periods of temporary congestion of new offerings or of severe bond market deflation, calls for a very large increase in these loans, as the amount of unsold securities in the hands of investment banking houses is at such times abnormally high. Although investment banking houses do not as a rule publish statements showing their income accounts or balance sheet position, profits are known to vary widely with changes in security market conditions. Costs in relation to the volume of business handled are smallest for wholesale houses and those specializing in selling to financial institutions, while they run highest in houses engaged in retail distribution to the small individual investor. They are very high in the case of small and highly speculative issues, which, however, are generally avoided by large

and well established banking houses. In these issues high pressure salesmen or aggressive mail order advertising campaigns are used to reach small buyers; the greater and more expensive effort needed to effect distribution is balanced by a very wide spread between purchase and sales price.

The outstanding peculiarity of investment banking practise in the United States as compared with that of European countries is perhaps this ubiquitous use of the security salesman, a practise which developed from the aggressive "doorbell ringing" methods of selling first made prominent by Jay Cooke in Civil War days. Virtually all houses of any size engaged in retail security selling depend upon corps of salesmen, compensated in the main by commissions on actual sales, to keep in touch with clients and obtain orders. In continental European countries, on the other hand, security buyers are expected to come to their banks and investment houses to place orders; while in England brokers play a prominent part in retail security distribution by advising clients and taking orders on a commission basis for new offerings. Other features more or less peculiar to American practise in times of prosperity are the popular sale on a large scale of stock as well as bond issues, the speedy nominal "closing of the book" shortly after the offering, the pegging of prices through syndicate bids in the open market during the period of distribution and the development in recent years of periodical, billboard, radio and direct mail advertising of securities as a means of reducing the resistance met by the salesmen in effecting actual sale.

While the basic economic function of investment banking is to allocate the annual flow of savings to specific productive employment, it tends also by offering acceptable media for investment to encourage saving and hence to accelerate industrial development. The stimulation of investment thus attained is uneven; it is at its peak in periods of prosperity, for as soon as the public evinces a willingness to buy there is a general rush among investment bankers to create and dispose of new issues at a profit before the market becomes saturated. When the expansion in investment banking operations assumes the proportions of a boom in the security markets, the investment banking mechanism is all too likely to absorb an excessive proportion of liquid funds and short term credits in order to support investment in long term securities. At such times large scale purchases of securities

by banks and the sharp increase in security loans to individuals permit the investment banker to sell new issues on a greatly enlarged scale. The resulting rapid bank credit expansion for investment purposes, experience teaches, leads to maladjustment later, in the course of which the indebtedness is scaled down while the volume of new financing is reduced for a time to abnormally low levels. Investment banking also tends to strengthen large business units at the expense of the small: since large enterprises and combinations attract the attention and the confidence of the investing public, their securities are more readily marketable and because of their larger volume they can be handled at a smaller unit cost. The presence in a country of a highly developed investment banking organization hungry for business is thus an important stimulus to the expansion of established enterprises by the issue of more securities and an incentive to the formation of large scale combinations. In Great Britain, where the investment banking institutions have been traditionally engaged only in government and foreign financing, large scale enterprise and industrial rationalization have been relatively long delayed despite the fact that in the early nineteenth century British industry was in the van of progress by a wide margin.

The issue house, the central factor in the investment banking mechanism, exercises a dominant role in determining the distribution of new capital among various industries. In normal times important issue houses turn down far more individual applications for funds than they accept, selecting those which are likely to prove most attractive to the investor and which promise the greatest profit for the house. In order to protect their clients, to assure future control over financing and to profit in other ways investment banking houses have sought to gain control over large corporations by retaining large blocks of voting stock and by obtaining representation on boards of directors. In connection also with government financing the investment banker has frequently sought to be more than a merely passive agency for selling securities at a profit. At times bankers have dictated policies to political bodies as a price for their financial aid. Especially the governments of less well developed countries have had to subject themselves to a measure of control by investment banking houses floating their issues.

In the richer countries the search by invest-

ment bankers for new offerings with relatively high yields tends to turn their attention to foreign securities. Commercial and industrial groups often take the initiative in stimulating an export of capital, seeking to provide buying power for foreign customers by urging bankers to sell bonds for them. In many instances political and trade treaties, concessions, building contracts for public works and similar privileges for special interests have been sought abroad by big banking and industrial groups with loans as the consideration. The need for foreign capital in the economically less developed countries to finance government deficits, railway and other capital improvements and corporate development has made the international banker an important factor in the political development of the last century. In the United States the investment banker has often been guided solely by the desire to distribute at a profit what he considers a satisfactory security. In Great Britain investment bankers have sometimes attempted to foster specifically British exports, going so far in certain cases as to insert in the loan contract a "tying clause" earmarking the proceeds for the purchase of British manufactures. French foreign financing, on the other hand, has frequently been based on political considerations, the foreign office of the government working closely with the international investment bankers for this reason.

Investment bankers may also finance domestic corporations which acquire interests abroad and thus indirectly finance the export of capital. In such cases domestic corporations may float security issues designed to finance the construction of plants and other facilities abroad or the purchase of stock interests in foreign enterprises. In some instances separate corporations are organized to operate abroad. The International Telephone and Telegraph Company and the American and Foreign Power Company are outstanding examples of American corporations that have raised funds freely through security issues in the home market and have invested them in public utility enterprises in foreign countries. Occasionally such corporations develop into full fledged international finance companies. Companies of this type, which have been an important factor in the international migration of capital since the earlier days of the railway era, seek to combine the functions of security flotation with investment and direct participation in industrial management. They raise funds by selling their own securities in the

home market, supplemented at times by foreign issues as well. Capital so raised is then invested in foreign enterprises, control of which is often retained in whole or in part through stock-ownership or monopoly concessions from the government. The finance companies of the nineteenth century being interested in railway promotion often carried on also contracting and construction activities. Finance companies of the twentieth century, like the ill fated *Kreuger and Toll*, have fostered national industry, in which they participate by stockownership, through utilizing their investment resources to obtain new markets abroad.

Public regulation and control of investment banking are present to some extent in nearly all countries where it constitutes an important economic activity. A number of objectives are sought in public control. The effort to prevent security frauds has resulted in nearly every country in special legislation (known in the United States as blue sky laws) providing either for approval by a regulatory authority of new security issues before offering or for effective prosecution and punishment of fraud after its commission. Also legislation governing the organization, administration and financing of corporations is in part designed to prevent losses to investors through unsound or fraudulent practises in connection with promotions and security issuance. The fact that investors have suffered enormous losses in perfectly sound securities because of sharp declines in quotations during periods of major deflation has created another objective of control—stabilization within reasonable limits of security prices. During boom times this may take the form of restrictive central banking policies. During depressions the reverse policy of artificial easing of credit to encourage expansion of bank investments and loans as support for declining prices is frequently attempted. In certain countries efforts have also been made to attain a measure of stabilization through regulation of stock exchange practises.

A more fundamental objective of investment banking control is the allocation of capital among various prospective users in accordance with some preconceived plan. One instance of such control is that exercised by the Capital Issues Committee set up in Washington during the World War with power to pass on each new offering proposed. Because of the stupendous volume of government financing that had to be accomplished this committee sought to dis-

courage other issues as far as possible, except where they were regarded as necessary to finance industries which played an important role in the prosecution of war, such as the railroads, steel companies, munitions manufactures and the like.

Numerous proposals have been advanced to apply the same principle in peace time in the interests of more rational and stable economic development. During the post-war period several capital importing countries—Italy, Germany, Poland, Australia and Colombia—actually set up control over issues floated abroad. In Italy the minister of finance was given full control over all foreign borrowing in 1928. In Germany borrowing abroad by states and municipalities was made subject to approval by an advisory board of government and central bank officials; this body sought to restrict the import of capital as far as feasible to funds required for productive uses, so that the necessity to pay interest and principal would not constitute a dead weight burden on Germany's international balance of payments. In Italy, Austria and other European countries a large measure of state control over the flow of domestic capital was obtained during the post-war period through close cooperation of the government with large banking institutions. Such a policy has led, however, to the necessity for liberal government aid and intervention in depression periods to prevent the collapse of institutions which become overloaded with frozen commitments undertaken at the suggestion or behest of the state. Complete control over the flow of long term capital is now achieved only in Soviet Russia, where a portion of the national income is allocated each year to stated capital investments under a system of national planning and state control of industry.

INVESTMENT TRUSTS. Investment trusts are corporations, common law trusts or trustee funds set up to provide investors with the advantages of diversification and supervision of their investments. The sole objective of such trusts is cooperative investment resulting presumably in higher return with equal safety or in greater safety with equal return. Unlike holding, operating and finance companies they generally avoid the "entangling alliances" of management or control of the corporations whose securities they own and so limit their ownership in any one industrial, merchandising or public utility company that they may at any time quietly withdraw without sacrificing related interests or disturbing the market for the securities being liquidated. The preponderance of common stocks in portfolios of most American investment trusts has made more difficult any popular distinction between them and companies organized at least in part for quite different purposes. Terminology is less confused in Great Britain, where investment trusts own principally bonds and preferred stocks and show a wide distribution of risk in their limited common shareholdings.

In the historic Scottish and English sense investment trusts are more closely akin to savings banks or insurance companies than to holding, financing, operating or purely trading concerns. Like the former their appeal has been primarily to the thrifty who have built up estates by systematic saving and reinvestment. Any holder of investment trust securities other than debentures and notes is, however, in a very different position from the savings bank depositor or the insurance policyholder. Instead of being creditor for a stated sum of money under given conditions the investment trust participant is part owner of a fund of securities and cash; his immediate and ultimate returns vary, depending upon the ability and conservatism of the trust administration.

With regard to service investment trust funds and companies may be compared also with investment consultants. Here again, however, the differences are marked. The services of investment counsel may be relatively expensive and are necessarily limited to the wealthier investors. Investment counsel moreover possess varying degrees of authority in giving effect to their recommendations. In some cases their functions are advisory only; in others they are entrusted with complete administration. Participants in investment trusts possess only such control over management as is conferred by voting power of common stocks; while in uniform trust funds the beneficiaries, as long as they choose to hold their certificates of participation, have no control over the trustees. Investment counsel and trust companies in their accounts for private estates must as a rule administer each investment fund separately. Investment trusts rest upon the principle of mingled investments under responsible centralized supervision.

When properly run, investment trusts are the logical vehicles for middle class investors, enabling them to enter the investment arena on something approaching terms of equality with institutional investors and the rich whose capital is sufficient to permit large distribution of risk and employment of special financial counsel. This has proved true during the ups and downs of a half century of British experience, although in the United States certain varieties of investment trust were engulfed in the speculative mania of 1928-29 and departed very far from their proper purposes. Only half the truth would appear, however, if it were not recognized that the wealthy also have found investment trusts convenient and serviceable in building up

a backlog of safe investments which yield a larger return than government bonds.

From the point of view of the individual investor, particularly the inexperienced small investor, the theoretical justification for co-operative investment devices lies in the confusing variety of securities available for purchase, the technical character of modern investment markets and the need for expert guidance in interpreting business trends and critically analyzing corporate reports. From the social and economic standpoint investment trusts may be said to encourage thrift by making investment safer and more profitable and to attract the scattered capital of small investors who otherwise might hesitate to buy securities. By their own purchases and sales—and in Great Britain by the limited underwriting they do in new offerings of bonds which meet their investment requirements—investment trusts have accelerated the sifting processes by which investment markets distinguish between better and poorer grades of securities. Sales from their portfolios when prices are top heavy and purchases adding to their holdings when bargain levels obtain have generally introduced a steadying force into fluctuating markets. On the other hand, in the unusual situation in which investment trusts experience feverish growth and assume a speculative character their heavy purchases of securities on a rapidly rising market may prove an additional unsettling factor by aggravating the inflation of values.

Investment trusts originated in Great Britain around 1860 or even earlier. British investment trusts, however, did not assume real importance until they became actively identified with the rapidly increasing export of capital overseas in the period between 1875 and 1890; the identification of one with the other continued until the World War. Investment trusts assumed a position of leadership in discovering oversea investment opportunities and contributed materially to the consolidation of Britain's financial supremacy by mobilizing the resources of numerous small investors for purposes of capital export—a function which in France was performed by the banks. So important in this connection were the investment trusts that German imperialists urged (with negligible success) that similar companies were necessary for Germany to compete more successfully with England in the export of capital.

In the late 1880's public interest in British investment trusts reached feverish proportions

and a boom was ushered in accompanied by all the evils of mushroom growth. Investment trusts, which were organized so speedily as to outstrip the growth in the volume of good securities, purchased too freely on rapidly rising security markets and drove the prices of some securities to dizzy heights. The struggle to increase earnings and dividends during times of rapidly rising security prices led many trusts to use devious and unsound practises. In order to realize profits from financing, dealing, issuing and underwriting many companies created large numbers of new trusts, which engaged in a variety of promoting, financial and investment activities and created a pyramid of paper values. In some cases cash dividends were disbursed without allowance for market depreciation and without reference in the reports to the impairment of capital. Some of the trusts failed adequately to distribute risk, confining their investments to a single industry or to a narrow group of securities. A number of the early trusts were characterized by still another weakness, the lack of sufficient reserves built up out of current earnings. There were instances also of too high overhead, of excessive organizers' profits, of transactions which proved more advantageous to certain directors than to the investment trust and of failure to keep a sufficiently liquid position in view of the imminent price reactions. The new institutions also suffered from two kinds of undesirable directors: those whose eminence in other fields attracted investors, regardless of the directors' fitness for their new responsibilities; and those connected with banking houses which frequently used the affiliated investment trusts as a dumping ground for issues which the public failed to absorb.

The Baring crash in 1890 and the accompanying international disturbances revealed the glaring weaknesses and abuses of the investment trusts which had sprung up so rapidly in the preceding decade. During the five years following 1890 some investment trusts were reorganized or wound up; others were compelled to reduce or eliminate dividend rates and to write down capital. Large losses were incurred and public confidence was not restored until the end of the decade. Out of these experiences, however, there emerged tested principles upon which a sounder superstructure was erected. The example of several companies which had successfully overcome adverse conditions and made progress during this entire period was studied to advantage. It was recognized that to finance new and untried

enterprises, to originate securities and to serve as fiscal or management agency for industrial or public utility undertakings are functions separate from those of investment and should not be undertaken by investment trusts. Reports were submitted to investors revealing in a clearer and more detailed manner the financial and investment status of the trusts, and auditors became more exacting in their requirements. Unethical practises in this field are now strikingly absent. The satisfactory performance of investment trusts during the World War and the deflation following it served to increase the faith of the British public. It also emphasized the importance of such factors as purchase for investment values, wide distribution of risk, continuous supervision and freedom from domination by banking houses that would not scruple to place their own interests above those of investment companies with which they are associated.

Practically all British investment trusts, which are usually incorporated under the general Companies Acts, have outstanding debentures as well as preferred and common shares. Borrowing rarely exceeds in amount the aggregate of paid-in share capital; and debentures, perpetual and terminable, through issuance of which almost all borrowed capital is obtained, are protected by cash and security assets equivalent at cost to at least 200 percent of their outstanding face value. Share capital is raised as a rule in the proportion of £60 par value of preferred stocks for every £40 in par value of common, or "ordinary." Thus of every £2000 paid in there will frequently be found £700 to £1000 in debenture borrowings, £800 to £600 in preferred stocks and £500 to £400 in common.

The comparatively low fixed rates on the borrowed and preferred share capital, generally from 4 to 5½ percent, together with expenses of management averaging annually about ½ percent on invested funds can be comfortably met out of income from interest and dividends on the trust's holdings; net earnings resulting from employment of fixed cost capital thus increase the amounts available for distribution on the common shares and for building up of reserves. Advantageous as such a capital structure proves to owners of common shares in times of prosperity and stable security markets, it would be perilously top heavy in unfavorable financial weather except for the British practise of buying mainly senior securities, treating realized profits as capital rather than income, paying out in dividends less than the net earnings derived

from interest and dividend income alone and regularly building up reserves in the form both of surplus appearing under the capital and liabilities side of the balance sheet and of deductions made from the cost figures for investments on the assets side.

In fact there has developed in Great Britain a clear cut distinction between investment trusts and finance companies based mainly upon the arbitrary standard of the treatment of capital profits. Investment trusts are regarded as quasi-permanent investors in securities considered more or less as fixed capital. Sales and reinvestments are made as a rule in order to maintain or improve the quality of the portfolio or to increase the interest and dividend yield thereon and only incidentally to realize profits. Profits and losses on turnover are treated as capital items not subject to the income tax; they are run through a special hidden account separate from ordinary profit and loss, or income, statements and are used in very large measure for reducing the figure at which investments stand in the balance sheet to points often far below cost. Finance or trading companies, on the other hand, treat securities owned as stock in trade and actively buy and sell with the intention of making trading profits; such profits are regarded as income available for expenses and dividends and must be reported, with deduction of realized losses, as taxable income.

There are at present in Great Britain more than two hundred investment trusts with an aggregate paid-in capital well in excess of £319,000,000 derived from issuance of debentures, preferred and common stocks in approximate ratios of 40, 35, and 25 percent respectively. The holdings of each company vary from a hundred to a thousand different investments. As appears from the reports of eighty-three companies holdings are distributed between senior and junior securities as follows: bonds and debentures 41.7 percent; preferred stocks 23.6 percent; common stocks 34.7 percent. For seventy-one companies, whose reports permit such comparative surveys, the geographical distribution of holdings is as follows: British Empire (excluding Canada) 45 percent; continental Europe 18 percent; Latin America 16 percent; United States and Canada 14 percent; other countries 7 percent.

Few institutions closely resembling the British investment trusts are to be found elsewhere. Switzerland and Belgium especially offer notable examples of investment, holding and operating companies interested in rails, utilities and

industrials of many countries; because of the diversity of their holdings and the broad distribution of risk in their portfolios it might not be inappropriate to term some of these companies financing investment trusts. Yet important as have been the credits and investments extending across national boundaries and overseas of numerous banks and corporations in these countries and in France, Germany and the Netherlands, the organizations existing solely in order to diversify risk cooperatively and to provide investment supervision are conspicuously few in number.

In the United States and in Canada there has developed during the last eight years a formidable investment trust movement. The first attempts, during the World War and the early post-war period, to organize investment trusts in the United States were connected with the export of capital. Such attempts, however, were few and were for the time ended by the depression of 1921-22. Interest in investment trusts revived in 1924, but they did not become important until two years later. From then on growth was extremely rapid; within four years investment trusts were organized with resources exceeding \$3,000,000,000. Motives prompting the sponsors varied all the way from a desire to provide the public with sound cooperative investment facilities to a wild scramble for private profits, evidenced in high pressure salesmanship with its attendant abuses. Particularly as the speculative mania of 1928-29 reached fantastic heights, it became evident that an investment device thoroughly sound in principle was in many instances being distorted and misapplied by persons who lacked background, knowledge and in some cases even personal integrity—abuses which recall the vicissitudes of early British investment trusts as well as American experience in the field of mortgages, mortgage bonds and in earlier decades railways, public utilities and banks.

The development of American investment trusts, finance, trading and holding companies not only repeated the earlier British abuses but gave rise to entirely new ones based upon unsound holding company practises. Control of huge aggregations of capital for the purposes of manipulation and speculation was easily obtained in some instances by the issue of non-voting stock; the grant of large common stock bonuses, subscription rights and special voting privileges to promoters; and the use of the holding company controlling a series of subsidiary companies by credit pyramiding devices. Much concentration

of utility, railroad, banking or industrial interests was readily accomplished through capitalizing an almost blind public faith in anything bearing an investment trust label. Promoters' fees and management charges were very often excessive. A few trusts were disguised trading companies speculating in a riotously inflated stock market. Even at the height of the bull market in 1929 there were organized investment trusts which filled their portfolios with stocks bought at prices beyond any reasonable earning capacity. Bankers in some instances unloaded new issues upon investment trusts under their control or influence. Plain as was the earlier British evidence of dangers involved in close relationships between houses originating and distributing securities and investment trusts, it required the events of 1930-31 to give conclusive American demonstration that managers of such companies and funds must have no ulterior motives in their investment policies if they are faithfully to serve investors.

Despite their initial disappointments American investment trusts appear, when viewed in proper perspective, to be firmly established. Comparatively few outright failures occurred as a result of the stock market collapse, and many weak trusts were salvaged, at least in part, by mergers with stronger groups. In spite of heavy shrinkage in their assets investment trusts have largely maintained service on their outstanding debentures. From interest and dividend income many of them earn enough to pay preferred dividends, although in numerous instances these have been continued only after writing down of capital or have been discontinued because of shrinkage in asset values behind their outstanding debentures. Official investigations, including careful surveys by the New York State Bureau of Securities, have shown relatively few instances of deliberate fraud or dishonesty in management, although the New York state attorney general reported to the legislature in March, 1932, that only about half of the one hundred companies intensively studied were free of one or more objectionable practices in "dumping," borrowing and lending, inadequate reporting, speculative operations and dividend payments. The charge that price gyrations rather than stability of security values resulted from their activities is heard less frequently. It is more generally realized that mistakes of judgment in timing their purchases and sales, although largely negating any stabilizing market influences which the relatively modest capital of investment

trusts might even then have exerted, could not reasonably be blamed for the speculative orgy and its inevitable aftermath.

Very few of the American investment trusts have specialized in foreign securities, and those which had been large buyers of bonds or stocks originating abroad have greatly reduced their commitments, both absolutely and proportionately, since 1930. Nevertheless these companies were a factor of some importance in the pre-crisis export of American capital to South America, Japan and Central Europe, particularly Germany. Although no more than twelve or fifteen at the most have held really substantial amounts of German securities, their aggregate funds invested in that country have probably ranged between \$75,000,000 and \$100,000,000 and have represented perhaps as much as 10 per cent of their total holdings at cost. The natural bent of the American investor to place his funds in domestic securities has been fortified by the international collapse of business and credit on a hitherto unprecedented scale. As revival of confidence at home, however, must in some measure depend upon and accompany the same phenomenon in other countries, it does not appear likely that the future policy of American investment trusts will place a strong emphasis upon purely domestic holdings. On the contrary, it seems probable that some companies now functioning, as well as others which may be created as vehicles of international investment, will promote the export of capital and thus help to delay the conversion of the United States' favorable visible balance into the unfavorable balance which is normally characteristic of creditor nations.

There are several widely different varieties of investment trusts in the United States. The major types are the contractual (or trust) and the statutory (or incorporated) trust. The contractual investment trust is set up under a special contract, indenture or trust agreement, in accordance with the terms of which a trust company, a party to the trust contract, retains legal and physical possession of the securities or cash or both comprising the corpus of the trust and issues or authenticates certificates of participation. The most widely known investment trusts of this kind are the so-called fixed and semifixed trusts. They may be described as unit series in their make up, because the trust indenture describes a given unit of stocks against which certificates representing two thousand, more or less, pro rata shares are issued for public sale.

When the trust agreement prevents change in the composition of the unit (except in cases of mergers, reorganizations or liquidations) or merely allows eliminations without substitution of any other securities, the trust is fixed; when some leeway is given to make substitutions, whether under purely arbitrary or less exacting restrictions, the trust is semifixed or supervised, as the case may be.

The statutory (or incorporated) type comprises investment trusts organized under the general statutes of incorporation of the several American states or inviting public participation on substantially the same basis and by means of substantially the same kind of securities. Unlike the contractual (or trust) type these investment trust corporations (or Massachusetts or other common law trusts, which are operated like corporations) issue shares or stocks which are not redeemable or convertible like trust certificates; they are shares in an investment enterprise rather than merely certificates carrying a pro rata claim to trustee held units of securities or funds of securities and cash.

Besides the fixed, semifixed and supervised investment trusts of the contractual type, on the one hand, and managed investment trust corporations and Massachusetts trusts, on the other, uniform funds administered by trust companies or affiliates may be regarded as a form of investment trust. Such uniform funds include trust funds and incorporated funds. Uniform trust funds are the means by which several large trust companies enable their clients to share in jointly operated trust funds in minimum amounts too small to warrant an individual trust estate. Participation involves hardly any more formalities than signing a standardized trust instrument or becoming a party to the indenture under which the uniform trust is established by the act of subscription. Details differ, but the purpose is to give small estates the supervision and division of risk enjoyed by large ones. In uniform trust funds the participant, or certificate holder, is both beneficiary and remainderman; the trusts are revocable or the certificates redeemable at the option of the participants at their current values as determined in periodical revaluations. For technical reasons involving problems of taxation, accountancy and investment and distribution policies funds of this kind are not altogether suitable for that great majority of living or voluntary and testamentary trusts reflecting the peculiar requirements of each testator and separating the interests of life

beneficiaries and remaindermen. Application of the economies and advantages of mingled investment for the ordinary types of trust estate may be made more conveniently through an incorporated fund, especially if the trust officers plan an active supervision which will result in shifting investments, and aim both to build up reserves and to pay out distributions from income comprising profits as well as interest and dividends. The corporate form of uniform fund has been worked out by several leading trust companies and is being adopted or seriously considered by others; it is applicable, of course, only where permission to mingle is specifically given in the terms under which the individual trusts are established. No direct public participation is involved; these special investment corporations are merely convenient devices employed by the trust officers for trust estate investment. Complete service can thus be given to smaller voluntary or testamentary trust estates with less inconvenience to the trust officers and with the same attention as that enjoyed by the largest estates and a distribution of risk which is at least equal to, if not much greater than, theirs.

Insistent publicity has created the impression that fixed investment trusts include the bulk of American investment trust capital. That the enormous amounts paid in to companies of the managed variety in earlier years, however, leaves them still far in the lead is evident from compilations made in 1931, which show a total in round numbers of \$3,500,000,000 paid in to American investment trusts, of which approximately \$600,000,000 is for certificates in fixed and semifixed trusts. The \$2,900,000,000 of company capital may be split roughly into \$400,000,000 in debentures or bonds and \$2,500,000,000 in share capital. Although an indeterminate part of this gross figure may represent financing for holding or finance companies or for enterprises on the border line between these and investment trusts proper, it is still sufficiently impressive to illustrate the important if quiet role which such companies are playing today in American finance.

That this has been a passive rather than an active role since 1930 has been due primarily to two factors: the extreme difficulty of raising new capital, which has limited funds available for additional purchases; and the great depreciation as to both bond and stockholdings, which has raised the problem of absorbing realized losses resulting from sales either in the course

of reinvestment or in the process of repurchasing at a discount their own debentures and preferred stocks for retirement. The first difficulty will yield only with time; the second has been met to a degree by the establishment of special investment reserves to bear the impact of necessary losses in the readjustment of long range investment positions. These reserves have been created out of earnings, out of capital surplus arising from the writing down of stated values on paid-in capital stock and out of surplus resulting from purchase and retirement of the trust's own debentures and preferred stocks at prices less than par and liquidation values.

The New York Stock Exchange requirements concerning listing of investment trust company securities, while not insisting upon the separation from income of any realized profits or losses, have at least made it necessary, where such separation does not occur, to disclose clearly in the income statement the amount and origin of any drafts upon these reserves to cover losses over any fiscal period. The practise of excluding from income any cash losses or profits and running these through special reserve or surplus accounts is increasing. Not only are regular dividends to be largely divorced from fortuitous profit and loss on portfolio turnover, according to the Stock Exchange recommendations, but there are to be more frequent and complete accounting, proper exposition of consolidated positions and intercompany relationships, more conservative marketing methods, publicity of holdings and other practises emphasizing professional responsibility among directors and officers. These are all in accord with universal British practises, which also include making interest and dividends alone available for expenses and ordinary dividends, paying only cash on common and regularly reinvesting part of the earnings thereon, eschewing purely trading operation and recognizing the role of bonds and preferred stocks in any balanced investment position.

Of the fixed and semifixed investment trusts it may be remarked that many have improved their set up, presentation and sales methods as a result of the Stock Exchange rulings applying expressly to them. These offerings are not eligible, as are investment company stocks, for listing on the exchange. Association of member firms with them is limited, however, to an approved list of those which conform to requirements setting up new standards in the business. Appeal to

prospective investors on hypothetical charts of "what might have been" (in the highly improbable case that ten or twenty years earlier the identical list of common stocks comprising the present unit would have been chosen) has had to be abandoned. "Loading" and trustee charges have been more clearly expressed in order to permit comparison between offerings. Distinctions have been more clearly set forth between real income and return of capital in distributions made by those trusts which are required by their indentures to sell rights, stock dividends and split ups. There has been positive statement concerning disposition of interest paid by trustees on accumulations and on reserve funds paid in by the public.

One notable result of these requirements as well as of the changed position of many earlier "blue chip" stocks has been the issuance of new series by sponsoring groups for numerous fixed trusts. Not only has the principle of supervision been granted recognition by the dropping of old market favorites and the inclusion in the new units of stocks hitherto less popular, but the indentures have been drawn with greater care or amended with a view to a better definition of the trustee's responsibilities and a provision for his compensation during the life of the trust. Even more significant is the shifting of sales effort from the so-called distributive to the accumulative types. The former, it may be assumed, worked well enough when stock prices were high and markets were soaring. Now, however, the interests of the investor are presumably better served by conserving the results of stock split ups (if any), by saving stock dividends and by exercising rather than selling such rights as may accrue.

The efforts of investment trusts to put their own houses in order, spurred on by official investigations and encouraged by the constructive recommendations of the New York Stock Exchange, have done much to forestall drastic proposals made in various quarters for state regulation. While projects of varying tenor are still under consideration, the laying down of wise comprehensive codes could be exceedingly difficult without a broader background of American experience. Blue sky legislation in the majority of American states gives the commissioners certain powers in requiring reports and in ferreting out abuses, and it is likely that antifraud acts will be strengthened with specific reference to certain generally condemned practises. In so far as investment trusts and particularly holding

companies tend to increase the separation between ultimate ownership and control, it seems likely that federal and state regulation will be broadened and strengthened to take cognizance of their activities in the fields of banking, railroads and public utilities.

IONESCU, TAKE (Jonescu) (1858-1922), Rumanian statesman. Ionescu studied law in Paris and as a member of Ilfov's Bar Association entered the political arena with buoyant enthusiasm for the realization of the national aspirations of Rumania and for a program of social reform inspired by his admiration for France and Great Britain. He was the founder of the Democratic-Conservative party and served successively as minister of public instruction, minister of finance and minister of the interior. He was minister without portfolio from 1916 to 1918, minister of foreign affairs in 1920 and prime minister during the short crisis which extended from December, 1921, to January, 1922.

Ionescu furthered the social betterment of the peasant class by making primary education compulsory and by proposing in 1915 the agrarian reform, which was realized in the years from 1917 to 1921. His sympathy for the bourgeoisie moved him to advocate reformation of the inheritance tax (law of 1900), reduction of the legal interest from 5 percent to 4 percent (law of 1904), increase in the number of secondary schools and expansion of higher culture. He protected with equal vigor the political and civil rights of the Jews, defended freedom of the press and was influential in establishing universal manhood suffrage in 1917.

His political career culminated in the part he played in the national unity of greater Rumania. He aided the Transylvanian national movement despite the treaty of alliance of 1883 with the Austro-Hungarian Empire, secretly renewed after thirty years. At the negotiations for the Treaty of Bucharest in 1913 he secured the territorial expansion of Rumania into the Dobruja and from 1914 to 1916 he directed the campaign against the Central Powers. His famous parliamentary speech of December 16 and 17, 1915, brought Rumania into the World War on the side of the Allies. At the peace conference he was instrumental in securing the annexation of Bessarabia, Bukovina and Transylvania. Ionescu favored the creation of a Danube federation of the Balkan states but subsequently realized the impossibility of achieving this and

was instrumental in the formation of the Little Entente in 1920.

IRISH QUESTION. The *pax romana* was never troubled by the Irish question. Not that the Romans were unacquainted with the Hibernians; on the contrary, the evidence points to ever growing trade relations between Erin and Roman Gaul. Christianity was transmitted to Ireland by traders in the fourth century, paving the way for the work of St. Patrick and his disciples in the fifth. Simultaneously, although independently, Roman letters and Roman learning were conveyed to Ireland, perhaps by pagan scholars fleeing before the irruption of German barbarians into Gaul. The eventual fusion of saints and scholars engendered a monastic movement which played a basic role in the re-Christianization and reeducation of Merovingian Gaul and its Germanic annexes, offering formidable competition to the Benedictines and their Roman sponsor. Irish Christianity was not in close communion with the Apostolic See of Rome; Irish saints who were also scholars made their peculiar contributions to mediaeval Catholicism independently—notably the *Penitentials*, of which Gregory the Great was unaware. It was this isolation of Irish Christianity which in the seventh century first posed the Irish question in England. The *Book of Armagh* admitted of appeal to Rome from the successor of St. Patrick "if he cannot decide," but this measure of recognition of Roman headship did not suffice for the zealous emissaries working from Canterbury and faced with the rivalry of the Irish at Lindisfarne. At the synod of Whitby in 664 the intervention of an English king decided the issue against the Irish. It was the first but by no means the last time that England and the papacy were to see eye to eye in Irish matters.

In the ninth century the Celts of Erin had to deal with their first invaders. The Northmen, or Ostmen, established themselves in the chief ports from Dublin round by Waterford to Limerick; their walled towns, which frequently had Celtic antecedents, were soon incorporated as integral elements in the Irish political structure—a structure which had meanwhile been evolving, like that of Anglo-Saxon England, toward monarchy of a feudal type. The usurpation of

Brian Boru (1002), although it dispossessed the time honored dynasty of the Ui Neill and opened the way to other aspirants, perhaps gave greater reality to the office of high king. The economic conditions of the time did not permit of real centralization, but in the eyes of contemporary European princes the *magnificus rex Hiberniae* was the acknowledged ruler of all Ireland. The state of Ireland in the eleventh and twelfth centuries has been not altogether unjustly compared with that of the east Frankish kingdom after the disappearance of the Carolingian dynasty, where an elected king, himself a "stem duke," exercised a variable measure of authority over his fellow dukes, themselves eligible to election to the kingship. In the twelfth century, however, Irish saints and scholars set in train a movement that was to wreck the high kingship. The Cluniac and Hildebrandic reform movements, launched in Ireland by Bishop Gillebert of Limerick, actively propagated by St. Malachy of Armagh (d. 1148) and supported by the high kings, reached their climax at the synod of Kells in 1152, where a Roman legate bestowed the pallium on each of the four archbishops. Ireland of her own motion had accepted the whole program of ecclesiastical reform, but the fact weighed little with popes who had not the reasons for championing political independence that had prevailed in the cases of Poland and Hungary. Accepting at face value the clamorous accusations of Malachy and other Irish reformers, successive pontiffs abetted the Norman-Welsh conquest of Ireland, and thereby facilitated the surrender of its bishops and kings.

The conquest itself was distinctly unnational. Invited and guided by Irish Celts, led and commanded by Norman-French lords whose blood was mixed with that of the Celts of Wales, officered and manned mainly by Welsh and Flemings, Strongbow's force was anything but English. Henry, "son of the empress," followed less to reenforce the conquest than to curb his own vassals. Under Prince John Ireland bade fair to become a Norman sister to England; under John as king the foundation of an Anglo-Norman lordship in Ireland with institutions distinct from their English counterparts was continued; under the justiciar Wogan (1295-1312) the work reached its climax in the formation of a local Irish Parliament. In 1394 Richard II writing from Ireland summarized the situation: "There are in the land of Ireland three kinds of people; the wild Irish, our enemies; Irish rebels; and obedient English." The *irrois*

savages were the Celtic chieftains—O'Briens, O'Conors, O'Neils, O'Donnells and the rest—who although ever ready to make submission in return for confirmation of their land and authority were consistently striving to restore and expand the possessions of their septs; the *irrois rebels* were the "chieftains of English lineage"—Geraldines, Butlers, Burkes and lesser lights—who although ever ready to seize additional lands from "Irish enemies" were still more ready to resent the intrusion of fresh lords from England or attempts to govern Ireland from England. Of very different stuff were the *Englois obeissantz*, consisting mainly of the population of the Anglo-Irish towns; this population was a variegated composite of Irish, Ostmen, Flemish, Welsh, English and other elements bound firmly together by a common business interest. The feudal lords whether Gaelicized Normans or crossbred Celts could have no loyalty to England's king; the towns in Ireland as everywhere in mediaeval Europe were the foes of feudalism and the friends of centralizing monarchy. Anti-Irish only in so far as Irish spelled feudal, the townsmen passed the statutes of Kilkenny and similar defensive legislation. Far below these categories, almost beyond the ken of Richard II or of the chiefs who dickered with him, the mass of the Irish, the tillers of the soil, the drovers and laborers, remained little affected. Transferred from Irish bondage to Norman villenage, their numbers augmented by the depression of many free churls, the *betaghs*, or *hibernici*, possessed no rights, Irish or English, until—as was also the case with their congeners in England—the operation of economic changes wrought their slow conversion into a free rent paying tenantry dependent mainly on wages for their livelihood.

In the fifteenth century the English interest in Ireland reached its lowest ebb, and the rise of the new monarchy in England entailed a new, this time an English, conquest of Ireland. The Tudors in England using Star Chamber and Parliament to crush the survivals of feudalism were fain to use other tactics in Ireland. A Parliament of the "obedient English" of the four counties of the Pale—less than a twelfth of all Ireland—called in 1494 by the deputy Poynings, ratified for Ireland recent acts of the English Parliament and provided that in future all legislation of the Irish Parliament must have the prior approval of the English council. The Parliament of Ireland having thus surrendered its independence not to the English Parliament but to the English crown, the latter in its turn handed

back its powers, old and new, to the Geraldine Kildare. Unable as yet to cope with feudalism in Ireland, Henry VII left the Irish to "crown apes next" while he consolidated his position in England. Although the Butler-Geraldine feud and the headlong revolt of Silken Thomas in 1534 compelled the extension of the Pale to include most of Leinster, Henry VIII preferred to govern Ireland "by sober waies, politique drifts, and amiable perswasions." Nor did his emphasis on repudiation of papal supremacy in assuming the title of king of Ireland in 1541 meet with especial resistance from Ireland.

As Elizabeth became increasingly involved in continental politics, the attempt to rule Ireland through Irish chiefs broke down. Shan O'Neil denied the queen's right to make him a hereditary earl and, posing as a champion of Catholicism, intrigued with Guise and Spain, a policy imitated by other and lesser chieftains. Thus sprouted the religious branch of Gladstone's upas tree—a branch that was to flower in the penal laws and bear fruit in the "uncrowned king." While Englishmen despite the efforts of the Jesuits gradually abandoned Roman Catholicism, Irishmen clung to it as the badge of their special interests. The queen's answer was the policy of plantation and the reduction of Munster and Connaught. With the flight of the earls in 1607 the way was open for the plantation even of Ulster. The growth in James' reign of the agrarian branch of the upas tree did not stop there: gavelkind and tanistry were judicially pronounced invalid; Davies undertook a general examination of old Irish tenures and redistribution in fee among the former holders. The small freeholders, deliberately dispossessed, emigrated, were reduced to tenants or took to the wilds as "tories," forerunners of the Whiteboys. In certain areas the Elizabethan policy of "surrender and regrant" was superseded by widespread confiscation and systematic plantation. Yet the bulk of the land did not change hands, and the survival of brehon customs—later known paradoxically as the Ulster custom—left the tenants essential security; the position of the toiling masses, the cottiers, remained unaffected by the fortunes of their betters whether Irish or English. Commercial prosperity was deliberately fostered, especially by Strafford, in the interest of the revenues of the English crown, then so anxious to avoid financial dependence on the English Parliament; an Irish army supported by Irish money promised to be a strong prop to English absolutism. Irish Catholics suffered

fewer disabilities than English and only in political life.

Stuart prosperity bred Stuart loyalty. The insurrection of 1641, mainly of quondam landlords against plantation landlords, gave place to a far wider movement for the crown against the Parliament, although Owen Roe O'Neill still asserted an independent Catholic patriotism, which hampered Ormond's efforts. Cromwell in Ireland knew no distinction between royalist and Catholic. Unprecedentedly sweeping confiscation totally altered the agrarian problem: "Hell or Connaught," coupled with continental armies and American colonies, claimed the vast bulk of Irish landlords and tenants; the laboring cottiers remained to till the soil for Puritan warriors and London realtors. Trade and industry were annihilated by war and discrimination. Restoration brought fresh "settlement" of the land, which was restored only in small part to pre-Cromwellian holders; absenteeism mounted and insecurity depressed values. However alien themselves, the landlords welcomed the reappearance of an Irish tenantry; customary tenant right survived all storms, and Catholic disabilities did not extend to rights in land. The loss of population, hurtful to the landlords, seems to have benefited the cottiers. Trade and industry revived, again encouraged by the crown, although the English Parliament was now able to keep a watchful eye out for English commercial interests. Once again the Stuarts strove for the welfare of the "obedient English" of Ireland, and once again even conditional prosperity bred not nationalism but loyalty to the crown and hostility to the Parliament of England.

The triumph of William of Orange at the Boyne in 1690 ushered in a new era for Ireland, the rule of the English Parliament. The conquest was complete and was fully exploited by the conqueror. The English Parliament at once assumed—and in 1719 asserted—the right to legislate for Ireland. By English law Catholics were excluded from the Irish Parliament, and the latter was permitted to enact the penal laws. To reinforce the Protestant landlord garrison further confiscation of Catholics' land was accompanied by abolition of customary tenant rights. The Catholics, forbidden to purchase land or to lease it for long periods, were reduced for the most part to tenants at the mercy of Protestant landlords. These landlords, whose title rested on seventeenth century confiscations and whose ascendancy rested on the penal laws, were bound to loyal dependence on England.

The middle class, Protestant and Catholic alike, was simultaneously eliminated. William had promised: "I shall do all that in me lies to discourage the woollen manufacture in Ireland, and to encourage the linen manufacture there, and to promote the trade of England." The legislative destruction of the Irish woollen industry by the English Parliament in 1698 was but the chief of a series of measures which while tolerating distilling, the linen industry and the provision trade drove thousands of manufacturers of both creeds to France and other countries. In such an Ireland, ruled by a class of landlords largely absentee and almost exclusively Protestant, with a negligible middle class—save for the agents and middlemen of the landlords—and a hopelessly rackrented peasantry, there was no room for nationalism; neither 1715 nor 1745 produced a ripple in Ireland; like Swift and Molyneux before him, Lucas went unheeded.

The accession of George III heralded the birth of a new, non-Celtic although largely Catholic Irish patriotism. Disturbances in the American colonies impaired the market for Irish linens; worse, the revolution led to an embargo on Irish provisions, bringing distress and suffering to landlord and tenant. The Irish Parliament was moved in 1779 to demand free trade with England. Backed by non-importation agreements, the drilling of the volunteers and the inability to find Irish money to pay British troops, the demand was impressive; at war with France, England repealed her restrictions on Irish trade and industry; under further pressure the act of 1719 was repealed in 1782; and in 1783 the English Parliament completely renounced its legislative authority over Ireland. During the agitation of the "rival Harries"—Grattan and Flood—most of the penal laws had been repealed; the remainder soon followed, and in 1793 Grattan's Parliament admitted Catholics to the franchise although not to the legislature. A period of prosperity marked by resuscitation of Irish industry ensued.

Simultaneously had been born a very different movement. The Whiteboy disturbances, beginning in Munster in 1761 and spreading under a variety of names to other provinces, have been well described as the operation of "a vast trades' union for the protection of the Irish peasantry: the object being, not to regulate the rate of wages, or the hours of work, but to keep the actual occupant in possession of his land, and in general to regulate the relation of landlord and tenant for the benefit of the latter." At the same

time efforts were made to reduce or abolish the tithes to the Protestant clergy and to limit the fees of the Catholic priests. Economic distress enhanced by the rapid growth of the poverty stricken population took no heed of religion or politics save in the north; there the division of the lower classes into Catholics and Protestants made it possible to stimulate the latter against the former. The rise of the Peep o' Day Boys, later Orangemen, rallied the Catholics to the ranks of the Defenders, later Ribbonmen, and precipitated a long series of disturbances of religious color.

The French Revolution was echoed throughout the British Isles in the formation of republican secret societies; the chief Irish society, the United Irishmen, arose among the Presbyterians of Belfast. The appeal of liberty and equality was primarily to the middle class; the aristocracy and gentry boasted few such romantics as Lord Edward Fitzgerald. For these Jacobin enthusiasts the victory of 1782 was of small moment. Grattan's Parliament had two grave defects: it did not control the Irish executive—the "kingfishers"—and it remained a landlord assembly thronged with English placemen. Conscious of weakness in the face of a ruling class backed by a foreign government, Theobald Wolfe Tone, a Dublin Protestant accepted as leader of the movement, appealed to the peasants against the landlords: "Our independence must be had at all hazards. If the men of property will not support us, they must fall; we will free ourselves by the aid of that large and respectable class of the community,—the Men of no property." The peasantry, flattered by the unusual attention of their betters and as in France ready to embrace the opportunity to remedy their grievances on an exceptionally generous scale, rallied to the cause; the Defenders were partly absorbed into the United Irishmen, and Whiteboyism ventured into new fields. From its new allies the movement suffered more than it gained: the Presbyterians tended to draw back in alarm; agrarian disturbances enabled Fitzgibbon to intensify repression. French expeditions ended in disaster, and Tone escaped the gallows by Roman suicide in prison; his associates paid on the scaffold for the insurrection into which they were driven in 1798. The union was bought, if not fully paid for, and Robert Emmet's brief flare was speedily extinguished.

In the first half century after the union the Irish upas tree speedily put forth a verdant foliage, its three branches—agrarian, religious

and educational—sturdily supported by the ancient political trunk. The roots lay deep in Ireland's past, but the mature verdure of the nineteenth century was of a hue not conspicuous in earlier Irish landscapes. Throughout Irish history the agrarian question had risen from the struggles among landlords past, present and prospective. The completeness of the Williamite conquest and the subsequent proved stability of the British government had removed all fears of fresh confiscations. By the end of the eighteenth century existing Irish land titles might be regarded as secure. But the very security of the landowner, coupled with the effects of capitalistic economy, increasingly forced to the fore a new agrarian problem—the problem of relations between landlord, tenant and laborer.

At the time of the union there existed a marked tendency in the direction of small holdings, due principally to the operation of Foster's corn law of 1784 but stimulated by the admission of Catholics to the franchise in 1793; the one factor put a premium on tillage, the other on the number of forty-shilling freeholders on a landlord's estate. The "peace without a parallel" and the consequent fall of grain prices, coupled with the landlords' unwillingness to adjust rents correspondingly, produced a marked tendency to clearances. Heightened by the disfranchisement of the forty-shilling freeholders in 1829, clearances were to reach their climax with the famine, being further encouraged by repeal of the corn laws in 1846, by the new poor law of 1847 and by the Encumbered Estates Act of 1849. Absenteeism mounted sharply after the union. Agents and middlemen in a seemingly endless chain extracted the utmost in rents, fees and services from the tenants, holding arrears always over their heads; cottiers paid in labor for their conacre holdings. Leases for short or indeterminate periods prevailed; in 1847 the Devon Commission reported: "The greater portion of the occupiers of land in Ireland hold as tenants from year to year." Except in Ulster compensation for improvements was unknown; at the first opportunity the land was "canted" to the highest bidder. To Nassau Senior "the treaty between landlord and tenant is a struggle like the struggle to buy bread in a besieged town or to buy water in an African caravan." Against the evils of rackrenting the laborers and poorer farmers, who were also laborers, continued to react in Whiteboyism, although they were unable to bring the agrarian question to the pass at which Gladstone felt constrained to set himself the task of defining and

redressing Irish grievances. Whiteboyism in its various aspects lacked the cohesiveness of a definite organization, although its sporadic manifestations seem to have been linked by potato vine telegraphy. Only in connection with the tithe agitation of 1831-32 did Whiteboyism reach the proportions of a national movement, a movement shadowed by the religious as well as the agrarian branch of Gladstone's trifurcate upas tree.

The religious question was partly political, partly agrarian. Grattan's Parliament had repealed the penal laws and admitted Catholics to the franchise; the union had failed to fulfil the hope of Catholic emancipation. Although upper class Catholics had resented the continuance of their political disabilities, it remained for a popular demagogue to make Catholic emancipation an issue. Thwarted in his own political ambitions, a middle aged criminal lawyer named Daniel O'Connell founded the Catholic Association in 1823. The established Protestant church of Ireland was not merely endowed but empowered to levy tithes on all occupiers of land of whatever creed. Tithes and parish cess had long been objects of Whiteboy attack; not infrequently these grievances had been employed by landlords and middlemen to divert peasant attention from their own rack rents. Momentarily coupling religion and economics for a political end and aided by his stormy bilingual oratory O'Connell carried the county Clare in 1828. Fearing revolution the tories yielded; the "uncrowned king" entered Parliament at the price of the disfranchisement of six sevenths of the Irish electorate. To reward the peasantry O'Connell guided the "tithe war," which ended in 1838 after minor concessions, in the comedy of commutation; the landlord paid the tithe for the tenant and increased the rent. Shifted from the religious to the agrarian account the question lost interest for the Liberator, who bent his efforts to stamping out Whiteboyism and Ribbonism along with trade unionism and Chartism.

The third branch of the upas tree, the education question, was a more slender growth. While the "national schools" were successfully combating the survival of Gaelic speech, higher education in Ireland was virtually open only to Protestants, through Trinity College, Dublin University. Presbyterians preferred to go to Scotland, Catholics to the continent, although Maynooth existed with state aid to educate Catholic priests. In 1845 the Maynooth grant was more than doubled, and three non-sectarian

"godless colleges" were established, a measure which failed to solve an essentially religious question.

One other branch of the Irish upas tree, the problems of trade and industry, completely escaped Gladstone's attention, perhaps because its leaflessness permitted it to be obscured by the thick foliage of the other branches. "The Union dealt a heavy blow to trade," as O'Connell phrased it. The textile industries, temporarily and partially protected by the union duties, suffered rapid decline on their withdrawal; everywhere domestic hand loom workers were thrown out of employment; only in the north did a new linen industry grow up on a factory and machine basis. The provision trade and its dependent industries declined as the exportation of livestock was resumed. The handicrafts, which had flourished under Grattan's Parliament, were ruined by the removal of the seat of government from the Liffey to the Thames. Only brewing and distilling, the former almost exclusively for export, prospered. Whatever other factors may have played a role, it is fairly certain that lack of capital in Ireland—indeed the virtual impossibility of accumulating capital save in the north, where the Ulster custom prevailed—was of basic importance. Such industries as were established in Ireland, particularly before the removal of the union duties, were mostly established by Englishmen. Englishmen, however, had little incentive to invest in Ireland: the possibilities of profitable industrial investment in England itself still seemed inexhaustible; employers of labor were especially deterred by the reputation of the Whiteboys as a ready school for industrial trade unionism. In this latter opinion English manufacturers were encouraged by O'Connell's denunciations of Irish combinations.

The absence of industry while it intensified the agrarian problem also made for the weakness of the middle class, and this fact in turn meant the continued absence of serious nationalism. The day had not yet come for tenants and laborers to make common cause and unfurl the banners of nationalism in a struggle for agrarian reform. Herein lay the secret of O'Connell's power. He had accepted the disfranchisement of the peasantry. The handful of urban workers had never enjoyed the franchise; although they were organized in combinations, he could afford to defy and denounce them. Concerned mainly with strengthening his "tail" in Parliament and controlling the Irish patronage, King Dan was no enemy of the established order. Davitt, the

greatest foe of landlordism in Ireland, yet an ardent admirer of O'Connell, acknowledges that "he cannot be classed among those who have fought strenuously against landlordism"; nor could anyone charge O'Connell—for whom Unitarian and Dissenting mill owners in Manchester in 1836 raised a purse of £700, and who "would to God, children of thirteen years old in Ireland could earn the money which the English factory children might have earned" save for Lords Althorp and Ashley—with having been a foe of capitalism. Politically as well as socially O'Connell was conservative in the extreme. He rejoiced that he "kept Ireland free" from the "pollution" of the Chartists. Successive repeal associations were organized for an object which the "uncrowned king" himself stated to be "not worth the price of one drop of blood." His slogan, "Ireland for the Irish—God save the queen" is reminiscent of the policy of Strafford and Ormond.

Under the wing of the Repeal Association, however, there blossomed in the 1840's a vigorous nationalist movement. To be sure, Young Ireland was more in tune with the European *Zeitgeist* than with the conditions of the moment in Ireland. Inspired by Davis, guided by Mitchel and rationalized by Lalor, the movement even in its very name reflected continental stirrings rather than the aspirations of any social class in Ireland. Renunciation of England and all her works was the prime article in the catechism. Thomas Davis, poet and idealist, reacted violently against the idea that the factory system would benefit Ireland: "Oh, no! Oh, no! ask us not to copy English vice, and darkness, and misery and impiety; give us the worst wigwam in Ireland and a dry potato rather than Anglicise us." John Mitchel, chief of the Young Irelanders, who at the outset conceived of the nationalist movement as necessarily embracing all classes of the population, eventually adopted Davis' characterization of the landlords as a "filthy mass of national treason." Ardent republican and advocate of "public opinion with a helmet on its head," he was deemed worthy of transportation for fourteen years. But although his virulent Anglophobia led him to rejoice that the French insurgents of February, 1848, had renounced competition and free trade "in the sense in which an English Whig uses these words," the June days left him positive that "Socialists are something worse than wild beasts."

Of the Young Irelanders the clearest and most vigorous thinker was Fintan Lalor. Lalor defined

the spirit and aim of Young Ireland as "not to fall back on '82 but act up to '48 Not the constitution that Tone died to abolish, but the constitution that Tone died to obtain, independence, full and absolute independence, for this island, and for every man within this island." Lalor, like Tone, had no hope of countenance from the Irish aristocracy; from the middle class he hoped for sympathetic assistance, but it was to the peasantry that he turned to give the necessary drive to the movement. "The principle I state and mean to stand upon, is this, that the entire ownership of Ireland, moral and material, up to the sun, and down to the centre, is vested of right in the people of Ireland; that they, and none but they, are the landowners and law-makers of this island For let no people deceive themselves, or be deceived . . . by constitutions . . . and franchises. These things are paper and parchment, waste and worthless . . . those who own your land will make your laws The rights of property may be pleaded Against them I assert the true and indefeasible right of property—the right of our people to live in this land, and possess it."

Lalor's teachings were not fully appreciated by his associates; national not social revolution was their goal. In any case the time was badly chosen for revolution; as in 1798, it was foreign example not native ferment that produced the Tipperary rising of '48. The famine and famine fever of '46 and Black '47 had left the peasantry no energy to expend in revolt; misery and despair counseled emigration, and in a decade Ireland's population was reduced by one fourth. Interesting as a projection of the ideology of individual nationalists, Young Ireland cannot be accounted an Irish national movement. The mass of the peasantry was powerless to help or hinder this non-sectarian movement; the property qualification for the franchise was further raised in 1850, and the electorate continued to support O'Connell's band, known, now that the maestro was dead, as the Pope's Brass Band.

In the second half of the nineteenth century the Irish upas tree came to full growth. If its foliage was less verdant, its poison sap ran strong and proved the bane not only of successive British ministries but of Gladstonian Liberalism itself. Emigration, always a conspicuous Irish phenomenon, became a constant factor; although a few towns grew slightly, the heavy drain of population from the countryside produced a steady diminution in the general density of population. Notwithstanding the continued decline

of agriculture in favor of pasturage, reduction of population tended to effect reduction of the pressure for land; the peasantry was therefore in a stronger position for an economic struggle against landlordism, which with the disappearance of the middlemen loomed ever more prominently as the national grievance. In the years immediately following the famine—during which the Liberator's son had publicly averred: "I thank God I live among a people who would rather die of hunger than defraud the landlords of their rent"—Gavan Duffy's all Ireland tenant right movement was inevitably aborted; but the time gradually ripened for the more prosperous tenants to make common cause with their less fortunate fellows.

Emigration, which to some minds offered a happy solution for the Irish question, proved to be a complicating factor of far flung implications. Overseas and particularly in the United States the Irish reaped fulfilment of the angel's promise to Abraham. Whether by politics and contracts or by means more devious many out of their multiplying millions equipped themselves to possess the gates of their never forgotten enemies. The Ribbonmen, who after the Tithe War had gradually absorbed most of the Whiteboy elements, disappeared from Ireland to reappear as the Ancient Order of Hibernians. In time this and other Irish-American organizations were to play a vital role in Irish affairs.

This by-product of emigration soon nurtured disturbing fruits. In the American Civil War many Irish had fleshed their swords; their commissions dazzled the eyes of surviving revolutionists in Ireland. In 1858 James Stephens, a disillusioned Young Irelander, had founded in Dublin the Irish Republican Brotherhood; a few years later a cognate Fenian society was formed at Chicago. Deliberately the Irish Fenians through the newspaper which was founded to serve as the public organ of their secret society appealed for the aid of "the blistered hands of labour." "It is a waste of time and labour, or worse, to endeavour to arouse the upper and middle classes to a sense of the duty they owe their country." With the farmers the Fenians had little to do; their agitation centered in the towns among the artisans and laborers, with the result that in the 1860's the landlords enjoyed a temporary surcease from agrarian disturbances. The Fenians were not socialists even in the limited agrarian sense of Lalor; their program was purely and romantically nationalistic. Inspired by the news from Russia and fed with

tales of the thousands of armed men ready to sail from America, the I. R. B. plotted dire conspiracies, which eventuated in the pitiable collapse of 1867.

Yet Fenianism produced results in England, in Ireland and in America. In England Gladstone was moved to attempt the felling of the upas tree. Characteristically the Liberals addressed themselves first to the religious question. In 1869 the Protestant church of Ireland was disestablished and in part disendowed; in the general readjustment the Maynooth grant and the larger *regium donum* to the Presbyterians were abolished; the measure interested churchmen, Orangemen and Catholic bishops but left the mass of the population unmoved. The Land Act of 1870 did not accept what the Liberal prime minister in 1864 had called "communistic views disguised under the term of tenant right"; it merely legalized the Ulster custom in so far as it was practised and provided compensation for improvements if the evicted tenant could afford to prosecute his case in the courts. The Irish University Bill of 1873 was defeated with the aid of the Irish members. With the branches trimmed Gladstone hoped to remove the political trunk by continued coercion. In Ireland the amnesty agitation for the release of Fenian prisoners swept Isaac Butt into the leadership of the Irish parliamentarians. Under his cautious guidance Irish members at Westminster adopted the policy of independent opposition. To pressure for a federal solution of the political problem, for which the epithet home rule was coined, Butt linked a revived agitation for tenant right, which crystallized as the demand for the "three F's." In America Fenianism produced the Clan-na-Gael, ever a ready supporter of revolutionary agitation for Irish independence.

Michael Davitt, a Fenian, was chiefly instrumental in effecting the close cooperation between agitation in Ireland and Irish organizations overseas. The "new departure" of 1878, which put at the disposal of the leaders in Ireland generous sums of American money, coincided with the supersession of Butt by another Protestant champion of home rule; Parnell and his lieutenants at once embarked on the policy of obstruction in Parliament, driving out of the organization the more moderate of Butt's following. In America Davitt's proposals met with a response embarrassingly overenthusiastic. The American revolutionary Irish had no sympathy with mere parliamentary agitation as a substitute for revolutionary conspiracy but were more than ready

to welcome vigorous agitation against landlordism. In 1879 shortly after Davitt's return from America the Land League was successfully launched in Mayo, whence its operation soon spread to other parts of Ireland. In the antipodes as well as in the United States supporting land leagues were formed; the *Irish World*, the Clan-na-Gael and the A. O. H. poured money into Ireland. The Land League campaign differed in many essentials from the earlier White-boy disturbances; the movement attracted all elements of the peasantry, including the more well to do farmers; its methods despite the horror excited by the new word boycott were in the main legal; it worked in the open, countenanced by Parnell and other Irish political leaders and even by one of the archbishops. Rome's attempts to interfere against Parnell and the Land League tended to "make Peter's pence into Parnell pounds." The land agitation, with its slogan "The land for the people," was the most revolutionary movement in nineteenth century Ireland. O'Connell had intimidated the Iron Duke, but it needed Michael Davitt, the friend of Henry George, to convince English Liberals that under certain circumstances a man might not do what he would with his own. The Land Act of 1881 embodying the principle of the "three F's" established a dual property right in the land. Although unsatisfactory to the Land Leaguers—and still more to the Parnellites, unable to admit that any good could come from a parliament at Westminster—the act, followed in 1885 by the Ashbourne Land Purchase Act, went far toward removing the grievances of the more prosperous farmers. Something was also done for the agricultural laborers by the series of laborers acts beginning in 1883.

The politicians, who had curbed Davitt's enthusiasm for a no-rent campaign before the passage of the Land Act, found the weapon a failure when used for purely political ends. Hampered by the Phoenix Park murders, the Invincibles and the suppression of the Land League, the constitutionalists almost regretted that they had ever hearkened to Davitt's ringing denunciation of a policy that would ask "our peasantry to plod on in sluggish misery from sire to son, from age to age, until we by force of party power may free the country." The Parnellites had failed to wreck the bill, but the circumstances of its passage and the coercion policy that accompanied it fed the agitation, assisted by the revival of the National Land League as the National League. Extension of the franchise in 1884-85 merely strengthened

Parnell, who steadily augmented his phalanx at Westminster. In 1886 the impossibility of forming any ministry without Irish support impelled Gladstone's Liberals to commit political suicide by sponsoring the First Home Rule Bill.

For an almost uninterrupted period of twenty years of "resolute government" the Unionists strove to "kill Home Rule with kindness." Their initial Land Purchase Act was amended and extended, culminating in the Wyndham Act of 1903. The fundamental difficulties of the small holder, which lay beyond the direct reach of government, were recognized in the creation in 1899 of the Department of Agriculture under the guidance of Horace Plunkett, since 1889 the apostle of cooperation. The Local Government Act was extended to Ireland in 1898. The Irish, however, remembered the kicks and forgot the kindness. Although the Parnell split of 1890 was but ill healed by the recognition of Redmond's leadership in 1900 and although funds from America temporarily dried up, the Nationalist party continued to be the chief vehicle of Irish political expression. Ignored by the renascent Liberals, save for the passage of the virtually non-partisan Birrell University Act of 1908 and a few acts in further remedy of details of the land problem, the veterans of Parnell's struggles were enabled by the parliamentary situation consequent on the elections of 1910 to wring from England the goal of their ambitions—the Home Rule Act of 1914, providing for the establishment in Dublin of a parliament frankly subordinate to its parent at Westminster.

If the Nationalist party reflected the national aspirations of Ireland, the aspirations of Irish nationalists were finding expression in the Irish Ireland movement. Landlordism had suffered a mortal blow; slowly but inevitably it was being extirpated in Ireland—on terms which left ex-landlords and ex-agents the wealthiest and socially most considerable class in the country. The Church of Ireland had been disestablished, but the Protestant ascendancy remained socially intact. Although the local government patronage was surrendered to the Catholics in 1898, the "county class" retained its impregnable position. At the same time the material improvement of the farmers' position was reflected on the shopkeepers; manufacturing industry outside the Belfast area made little progress, but an important and well to do middle class developed. Not being gentlemen, the middle class youth must find some new avenue to social standing; and this they sought in Irish Ireland. The Gaelic Athletic

Association founded in 1884 excluded agents of the Castle garrison from its clubs and strove to place hurling and "Gaelic football" on a level superior to tennis and cricket. The Gaelic League founded by Douglas Hyde in 1893 preached the superiority of the Celtic language and literature to the Saxon; in 1913 the National University made Irish technically compulsory. A new school of Irish literature, using admirable English, clothed Irish mythological figures in Grecian garb or wove dramas racy of the soil. In 1896 an immigrant son of an Irish emigrant, James Connolly, attempted the formation of an Irish Socialist Republican party; from 1898 to 1903 his *Workers' Republic* preached Karl Marx in Celtic terms, spiced with emphasis on Tone and Emmet, Mitchel and Lalor. Another returned emigrant, Arthur Griffith, through the pages of the *United Irishman*, later *Sinn Fein*, preached his fanatically narrow "Hungarian policy," derived mainly from Friedrich List and Ferencz Deák; least national in its conception and policy of all the phases of the Gaelic revival, Griffith's organization was destined to become through the operation of forces which he labored vainly to combat the dominant mouth-piece of Irish nationalism. Even in 1910 the republican left wing of Sinn Fein through *Irish Freedom* lent countenance to what Griffith venomously dismissed as "English trade-unionism in Ireland" and queried the patriotism of Irish industries built on underpaid labor. Although insisting that "the independence of this country is the first practical step towards the building up of a decent civilisation," *Irish Freedom* viewed the Dublin labor war of 1913 as a "spiritual revolt"; like the young Irelanders, the republicans were prepared to hate "imported" capitalism. It was mainly members of this group who with a few survivors of the I. R. B. and a large following of constitutionalists organized in 1913 the Irish National Volunteers, the grateful response to the inspiration provided by Carson and the Ulster Volunteers; control was soon taken over, however, by Redmond and the parliamentary party.

Far different was the reaction to capitalism of another element in twentieth century Irish nationalism. Trade unionism in Ireland had been a spontaneous growth closely akin to trade unionism in England; its progress had been aided by the progress of the larger movement, for English trade unions in self-protection had found it expedient to build Irish branches. An Irish Trades Union Congress founded in 1894 had functioned

virtually as an adjunct to the Nationalist party. In 1907 the labor movement took on fresh life with the rise of Larkinism and the organization of unskilled labor. Fought by Griffith and Redmond alike, Larkinism developed a nationalism of its own, welcoming Connolly back from America in 1910. The great Dublin lockout of 1913-14 marked a vital turning point: the Trades Union Congress renounced allegiance to Redmond and formed itself into an Irish Labour party; Connolly, the nationalist, in Larkin's absence assumed direction of the Transport Union and its protégé, the Irish Citizen Army. Taking advantage of the split in the National Volunteers, Connolly and Tom Clarke, of the I. R. B., won the support of the republicans in Sinn Fein. Despite the frantic opposition of Griffith this triangular combination of organized labor, predominantly unskilled, of the old line physical force revolutionaries, who brought the money of the Clan-na-Gael, and of the Irish Ireland intellectuals who controlled the Irish Volunteers, sought to turn England's difficulty into Ireland's opportunity. The Easter rising of 1916 was foredoomed to failure, but its ruthless repression swung national sentiment from constitutionalism to warfare. A metamorphosed Sinn Fein gave birth to the Irish Free State.

The establishment of the Free State was strenuously resisted by fanatical republicans and rued by many who had looked forward to the establishment of a new social order. But although more potent than the penniless Communists, who welcomed the ripple of soviets of agricultural laborers and creamery workers, the Irish Republican Army, largely financed from America, could make no headway against the forces of Great Britain, whose artillery was now operated by men in the green uniforms of Saorstát Éireann. The labor movement, again dominated by the skilled workers, set its face against radical action. A Labour party in the Dail has not prevented the abridgment of British social legislation. The Free State quickly adopted tariffs and turned to the Shannon to aid industrial development; but it found that the consular service of Erin could for the most part be best handled by the British Empire. The remnant of the landlords were given short shrift; but British sports are embraced by gentlemen of a new definition, who may be sons of publicans. The Irish language has proved an embarrassment, although it had to be made an official language; literary ferment has been replaced by rigorous censorship; "Irish Ireland," the iridescent dream born of the ro-

mantic times of struggle, has become a nightmare in the mundane days of self-control. Religion, ever an extraneous injection into the material problems of Ireland, is not a present issue; with blatantly sectarian Northern Ireland on her flank the Free State has not yet followed the example of so many Catholic nations in open struggle with the church. The peasants and the shopkeepers, the bulk of the people, have inherited the land; to them as to Sydney Smith "Erin go bragh" has ever meant "Erin go bread and cheese."

An aberrant aspect of the Irish question is presented by Belfast. A portion of Ulster was so thoroughly planted at the beginning of the seventeenth century that a large proportion of the lower classes in that region is Scotch Presbyterian. The infiltration of Irish into the planted area could not be prevented; in particular the heavy emigration of Scotch-Irish to America in the eighteenth century opened the way for the return of numbers of Catholic Irish peasants. This fact gave a freakish twist to Whiteboyism in the north: the Presbyterian tenantry resented the competition of the Catholic Irish; under the name of Peep o' Day Boys, later Orangemen, they initiated a series of attacks on their rivals, forcing them to organize as the Defenders, later Ribbonmen. With the rise of industry in the Belfast area this guerrilla warfare of the two creeds was carried over into the ranks of the urban workers. The Ulster linen industry aided in the growth of the shipbuilding industry, the one employing the women, the other the men; the sexual division of labor and the temptation of an increasing family wage tended to depress wage scales and the position of the workers in general. To Ulster employers the creed of their workers was a matter of indifference, their wages a matter of vital importance. Elsewhere trade unionism might force wages up; but in Belfast, where with monotonous regularity religious processions provoked rioting between the two portions of the working class, trade unions found it difficult to function. Ulster business men feared economic separation from Great Britain and the rule of a farmers' parliament at Dublin; hence their enthusiasm for the Churchill slogan of 1886, "Ulster will fight, and Ulster will be right." To the Orange workers, whom Birrell described as having no more religion than a billiard ball, this meant simply "To hell with the pope." The rioting that year reached unprecedented dimensions. Twice, in 1893 and in 1907, the warring workers

fraternized openly, but these were special occasions that constituted reversals of the general rule. The "home rule means Rome rule" agitation and the drilling and arming of the Ulster Volunteers brought a return of the days of 1886. Ulster solemnly covenanted to prove her loyalty to Britain by resisting to the death the application of British law. The World War and the suspension of the Home Rule Act brought a reconciliation so complete that in the first years after the war a united trade union front forced wage scales even above Glasgow and Dublin levels. On July 12, 1920, at a monster mass meeting Carson carefully identified Sinn Féin, Catholicism and Labor as a trinity not to be tolerated "be the consequences what they may." The consequences were two years of violence, the expulsion of Catholics from virtually every form of employment, the disruption of trade union organization and the rapid decline of wage scales. In the meantime Ulster accepted the Better Government of Ireland Act of 1920 and sealed her separation from agrarian Ireland.

IRNERIUS (c. 1055-c. 1130), Italian jurist. Irnerius was born in Bologna, where he became professor of rhetoric and dialectic at an early age. His fame came to the attention of the countess Mathilda, who urged him to study law. His life from approximately 1076 to 1090 is a matter of controversy among modern scholars. Fitting and others (such as Besta, Palmieri and Vinogradoff) allege that he studied law at the school in Rome, where he later taught, and that about 1084 because of political strife he returned to Bologna, where after a period spent in research and writing he began to teach about 1090. The better view, advanced by Savigny and affirmed by Pescatore, Patetta and Kantorowicz, seems to be that Irnerius studied law as an autodidact at Bologna, working through practically all the *Corpus juris* before beginning to teach there. Documents from 1113 to 1118 reveal him acting in a judicial capacity; after a visit to Rome in 1118 he taught at Bologna until his death.

Uncertainty also exists concerning the works of Irnerius. All are agreed that he was the author of a great portion of the marginal and interlinear glosses to the *Corpus juris* and that he was the compiler of numerous *Authentica*, or notes, which made use of the constitutions in the Novels to indicate those statutes in the earlier compilations of Justinian that had been supplanted. Fitting edited and attributed to Irnerius works

of a different type, more comprehensive in scope and yet more theoretical in nature; for instance, the *Questiones*, *Summa codicis* and *De aequitate*. Others, in agreement with Fitting, have either edited or attributed to Irnerius works of a similar nature. Pescatore, Patetta and Kantorowicz deny that the edited texts were written by Irnerius, and Kantorowicz even holds that no works outside the glosses and *Authentica* were written by him, but that he did transcribe the so-called *Codex S* (now lost), the fount of all the vulgate manuscripts of the *Corpus*.

Irnerius' great contribution to jurisprudence was undoubtedly the establishment of the law school at Bologna, which focused its attention upon intensive study of Roman law and the development of jurisprudence in all its aspects. The personality and ability of Irnerius within a few years made Bologna the center of legal thought in Italy, and his students, the four doctors, extended its renown over Europe.

A. ARTHUR SCHILLER

Works: The glosses of Irnerius have been edited by F. K. von Savigny in his *Geschichte des römischen Rechts im Mittelalter*, 7 vols. (2nd ed. Heidelberg 1834-5) vol. iv, p. 458-70; by Gustav Pescatore in his *Die Glossen des Irnerius* (Greifswald 1888); and by Enrico Besta in his *L'opera d'Irnerio*, 2 vols. (Turin 1896) vol. ii. No mass of *Authentica* has been published. Doubtful works: Palmieri, G. B., *Il "Formularium tabellionum" di Irnerio*, Appunti e documenti per la storia dei glossatori, vol. i (Bologna 1892); *Questiones de iuris subtilitatibus des Irnerius*, ed. by Hermann Fitting (Berlin 1894); *Summa codicis des Irnerius mit einer Einleitung*, ed. by Hermann Fitting (Berlin 1894); "Summa institutionum" in *Scripta anecdota (antiquissimorum) glossatorum*, ed. by G. B. Palmieri, 2 vols., *Bibliotheca Iuridica Medii Aevi* (rev. ed. Bologna 1914) vol. i, p. 269-476.

HISTORY AND PRESENT ORGANIZATION. Although it is the center of a galaxy of industries, the heavy iron and steel industry comprises the normally integrated processes of smelting, refin-

ing and shaping iron and steel. Its products—pig iron, and semifinished steel in the form of ingots, structural shapes, bars, tubes, rails, plates, strips, sheets, wire rods, forgings and

castings—constitute the raw materials for further fabrication by the metal or engineering trades, from which the heavy iron and steel industry is to be distinguished. Because of its unusually great integration of operation and concentration of control the industry includes many other related activities. All of the larger companies mine their own ores and fuels, most of them operate extensive transportation facilities, while some embrace under unified control all the related and essential processes from mining to the final manufacture of ordnance, the construction of ships and the output of other products. In addition the industry has many by-products. Thus in 1930 the United States Steel Corporation controlled from one sixth to one fifth of the American production of Portland cement utilizing its own blast furnace slag; the industry furnishes the bulk of the important coal and tar by-products of the coking process and a substantial volume of gas for light and power.

Iron especially in the form of steel provides the structural basis of industrial civilization. Iron and coal are inseparably associated with modern technology and have been decisive instruments in the growth of capitalism, particularly since their technological interlocking in the modern steel industry. It is this development which has made possible the intensive exploitation of the mineral accumulations of the ages and the tremendous acceleration in the rate of production and consumption which underlie the recent development of industrialism. The increasing consumption of iron and steel measures the onward sweep of the machine age. In the United States the industry produced 108 pounds of pig iron and 34 of steel per capita in 1878, 638 pounds of pig iron and 592 of steel in 1909 and 786 pounds of pig iron and 1042 of steel in 1929—an increase of more than 500 percent in pig iron and nearly 3000 percent in steel. This enormous expansion in the output of iron and steel has been the primary factor in the conquest of industry by machinery, the growth of industrial integration and mass production, the concentration and trustification of industry, the great changes in consumer habits and the rapidly increasing urbanization of modern life.

In addition to the fact that it is the basis of other industries, the heavy iron and steel industry ranks among the foremost of the major industries in all highly industrialized nations. In the United States since 1919 iron and steel and their products have occupied third place in

the fourteen major industrial groups as classified by the census, exceeded in total value of production only by foods and textiles, although closely pressed by the machinery industry, and have alternated from third to fourth place in "value added by manufacturing." In 1929 blast furnaces, steelworks and rolling mills had an output comprising 5.9 percent of the total value of American manufactures and employed nearly 5 percent of the wage earners engaged in manufacturing. If machinery and allied products are included, the iron and steel industries surpass all others in value of production.

The almost infinite diversification in the modern use of steel—in the metal trades, in the manufacture of machinery, automobiles and ordnance and in thousands of other major and minor uses—is one of the most characteristic aspects of the steel age. All industries are dependent upon iron and steel either for machinery or raw materials or both. In the United States for the ten-year period 1922 to 1931 the railroad, construction and automotive industries were the predominant consumers of steel, absorbing over one half of the total, as shown in Table 1. The sharpest increase in the consumption of steel was in the automotive industry because of its recent great expansion; in 1929 it consumed 52 percent of the output of malleable iron foundries as well. Greater consumption by the construction industry reflected not only the expansion in building but also the increasing use of steel as a substitute for other materials. The railroads have always been important consumers of steel, but their relative importance in the steel market declined seriously after the wartime shortage had been made up, as they were unable to extend their lines mainly because of increasing competition from alternative methods of transportation. On the other hand, agriculture has increased its consumption of steel as a result of the agricultural crisis and the decline in prices which has accelerated the pace of mechanization. Although a considerable amount of iron and steel appears in consumption goods, most of the product takes the form of capital goods, reflecting the enormous fixed capital requirements of modern industry and its essentially metallurgical character.

An important consumer of iron and steel which does not appear in the statistics on the distribution of its uses is the munitions industry. Especially since the introduction of firearms and ordnance iron has furnished the sinews of war and constituted the basis of mili-

TABLE I

PERCENTAGE DISTRIBUTION OF FINISHED STEEL TO PRINCIPAL CONSUMING GROUPS IN THE UNITED STATES, 1922-1931

tary power. Particularly in Europe the iron and steel industry has been intimately identified with the production of munitions and the growth of militarism. In the Franco-Prussian War the Krupp works' improved ordnance was an important factor in Germany's victory. The World War was fought with steel, and one of its prizes was the iron mines of Lorraine. The Central Powers could not have fought as long and effectively as they did had not Germany been the greatest steel producer in Europe mainly by virtue of the union of the iron of Alsace-Lorraine and the coal of the Ruhr within its borders. Lorraine had been taken from France in 1870, but the strategic industrial and military importance of the prize was not appreciated until years later. During the World War barbed wire for entanglements, steel rails for the roads of transport and pursuit, steel plates for submarines, armor for tanks and battleships, were as indispensable as projectile steel, ordnance, small arms and ammunition. Minor steel producing countries, such as Italy, were relatively ineffective because of the difficulty with which these essential supplies were obtained. The weight of the American industry decisively turned the scales in favor of the Allies. No modern nation can become a first class military power without a highly developed iron and steel industry.

Although iron has been of overwhelming economic importance only during the past one hundred and fifty years and steel only during the past fifty years, iron has been an indispensable element in technology since it was first smelted three or four thousand years ago. Technologi-

cally the importance of the metal lies in its abundance, its strength and malleability and in the fact that for many uses it has no substitute. The slow steady growth of the industrial arts is nowhere more clearly demonstrated than in the history of iron. Prehistoric fires probably drew iron from the rocks quite accidentally; iron tools were used by primitive peoples. The use of iron was preceded by the use of copper and bronze, although in some cases the order was reversed. In the primitive open forges and bloomeries the impurities of iron were slowly "burned" out and a disappointingly small amount of pasty metal—a variety of the modern wrought iron—was ready for hammering, drawing and shaping. Uniting the two primary stages of iron manufacture—smelting and shaping—the early iron makers fused and softened the balls of malleable iron and hammered out their own shapes and implements for industry and war. For thousands of years the open wood or charcoal fires of the forge, or bloomery, was the sole known method of obtaining iron, the only progress during that long period taking the form of minor improvements in the bellows and other auxiliary apparatus.

On the basis of these primitive methods (which still persist in remote parts of the civilized world and in economically backward countries) the ancient civilizations developed an important iron industry, which produced an excellent quality of wrought iron and steel used mainly in the manufacture of military and agricultural implements. The industry reached its highest development in the Roman Empire, with the main producing centers in Italy, Spain

and Britain. There was an active international trade both in iron ores and in iron products. In Roman Italy the craft of the smith was highly developed; production was commonly carried on in small shops with a single forge, an artisan and a few apprentices, and smelting and manufacture were combined with the sale of the final products in which the shops specialized. Implements were wrought by repeated heatings and forgings on individual anvils. Prices were high in contradistinction to those of copper; and the artisans were usually prosperous and occupied an important social-economic status. Although in some places manufacturers gathered many smiths together under one roof, the factory system in the iron industry was negligible. Capitalistic merchants, however, bought up part or all of the output of independent artisans and sold it throughout the world. The most important use of iron was in the manufacture of implements of war; the armies had their own smiths and the government participated in the industry, although it was left mainly to private enterprise. In the later Roman Empire the government took over the exclusive manufacture of arms and armor and concentrated it in large state factories.

During the Middle Ages both the technology and economic organization of the iron industry remained practically unchanged, except for the improvements in furnace construction, the introduction of the Catalan forge and of the use of water power in driving the bellows and the hammers. Great skill was attained by the Arabians, Spaniards, Germans and Swedes in the manufacture of iron, particularly in the making of swords and ornamental ironwork. The forges, however, continued to be highly wasteful of iron, fuel and labor. It was not until the fourteenth century that molten iron for direct casting was produced in improved smelting furnaces of European iron makers. This was accomplished by means of larger furnaces with higher stacks, by forcing an air blast into the furnace by the use of water power, and by better heat conservation—all the result of attempts to save fuel and labor. The first castings were of poor quality and the uses of cast iron were not at once appreciated. It was gradually discovered that iron smelted directly from the ores requires further refinement for the production of really satisfactory castings. This led eventually to the divorce of smelting and casting and the growing importance of iron founding. The origin of the blast furnace, a vertical cylindrical crucible in which iron is

separated from the ore by smelting in direct contact with the fuel and flux, is enveloped in uncertainty. In the latter part of the mediaeval period the Germans developed the *Stückofen*, an improved form of the Catalan forge which they had built to a height of ten to sixteen feet. This improvement was the direct antecedent of the blast furnace, which is known to have been used in Belgium about 1340. Smelting practise was improved and perfected during the fifteenth and sixteenth centuries by the Germans, Belgians and the French; and gradually the Catalan forge and its improved form, the German *Stückofen*, were both superseded by the charcoal blast furnace. The greater economy of fuel and labor, the larger output and the greater diversity to which the greater supplies could be put more than compensated for the dissociation of smelting from the forging of malleable iron.

During the sixteenth century the most important use of casting was in the making of cannon, which revolutionized the technique of warfare. The demand for more and improved cannon greatly stimulated the iron industry. At this time the industry had reached its highest development in Germany, both in quality and quantity of iron output. A considerable capitalistic organization prevailed in the mining of iron and the sale of the final products, although on a much smaller scale than in the production of silver and copper, in which the Fuggers operated mines, smelting works and rolling mills. It was from Germany that England imported the blast furnace and other improved methods of iron making.

The next phase of the development of the iron industry was bound up, both as cause and effect, with the industrial revolution, which was largely a revolution in metallurgy and power. By the beginning of the eighteenth century the primitive bloomery was obsolete in Britain; it was replaced by the more complex sequence of operations represented by the blast furnace, the forge and the rolling and slitting mill. The iron industry was third in importance among British manufactures, mining and smelting 180,000 tons of ore annually and giving employment to 200,000 people in mines and manufactories. But the industry was hampered by the "tyranny of wood and water"—wood to provide charcoal and water to transport raw materials and products and operate the hammers and mills and furnish the blast for the smelting furnaces. Establishments were therefore widely scattered. The extent to which industry was hampered by the scarcity of charcoal, because of deforestation

and restrictions to protect forests from further ravages, is indicated by the fact that only 17,350 tons of iron were produced in Britain in 1740. Pit coal was used in iron smelting by Dud Dudley as early as 1619 and the first Abraham Darby established the commercial use of coke in 1709, but it was not until sixty years later that coke came into general use in smelting despite the economic need for a new fuel. In the midst of its decline the British iron industry was revived and transformed by the introduction of mineral fuel in smelting, the application of the steam engine to furnish the blast and the rapid advance in mechanical engineering—all phases of the industrial revolution, for which more and cheaper iron was the indispensable basis.

During this period the great change in the refining and shaping of iron was initiated in 1784 by Henry Cort. Building upon the experiments of others Cort introduced the puddling furnace, which permitted the use of fuels other than charcoal and furnished hot malleable iron directly to the rolling mill in a single continuous process. Until then malleable iron had been made either by the direct process or from pig iron by reheating in the forge. Cort had been among the first to investigate the application of Watt's engine to the forge hammer. His inventions now substituted a reverberatory puddling furnace for the hearth of the forge, grooved rolls for the hammer and the chemical removal of impurities in the iron for the method of removal by sledging. The puddling furnace reduced the cost of manufacture and yielded a larger quantity and more uniform grade of iron; the new rolling mill could handle heavier blooms and greater lengths and could turn out a greater variety of shapes and sizes of rails, bars and plates than had hitherto been possible. The result was startling. Hitherto a tilt hammer had with difficulty produced a ton of bars in twelve hours; but now fifteen tons of puddled metal could be passed through the rolls in the same time, and iron produced with pit coal could be substituted for charcoal iron for all purposes except the manufacture of crucible or cementation steel.

Technological changes in the iron industry produced corresponding changes in its economic organization in Great Britain. While the industry nowhere passed through the guild stage prior to the factory system (the guilds of ironmongers were fabricators and not producers of iron) and was dominated by capitalists who owned more or

less extensive works and paid wages to workmen, it remained a relatively small scale and decentralized industry until the close of the charcoal era. With the breaking of the "tyranny of wood and water" by the use of coal adjacent to iron mines the scattered establishments gave way to large and integrated concerns which mined the ore and coal, smelted, refined, rolled and slit the iron in its finished form of plates and rods. Smelting and refining were again united in the new integrated processes. Iron-works were concentrated near the coal fields, larger capital was invested and single works frequently employed half a hundred or more men. Landed proprietors, who formerly had participated actively in the industry, now leased their coal and iron lands to industrialists and provided most of the fixed capital as absentee owners. Thus comparatively small capital of their own was required by the active industrialists, most of whom had been metal traders, as in the case of many successful craftsmen in Sheffield and Birmingham seeking control over sources of raw materials. As fixed capital requirements increased amalgamations became numerous, and the industrialists early formed associations to regulate the business. Profits were very large, both for the landowners and the active industrialists. Upon retiring many of the latter engaged in banking and financing, thus establishing an early and intimate association between the iron industry and finance.

Under the influence of its own higher productivity, declining prices and the demands for iron of an increasingly industrial economy, the iron industry expanded its output. By 1788 Britain's 59 coke furnaces produced 53,800 tons of pig iron as against 14,500 tons of charcoal iron made by 26 furnaces. The total output of pig iron in Britain increased from 68,000 tons in 1788 to 250,400 tons in 1806, Swedish and Russian iron were no longer imported, and the production of charcoal iron almost disappeared. Output kept on mounting, stimulated by the demand for munitions during the Napoleonic wars and the increasing use of the steam engine, machinery, water pipes and gas apparatus. The decline in prices resulting from greater demand and output was accelerated by increasingly higher productivity due to a series of mechanical and other improvements, particularly the Neilson hot blast introduced in 1828, a device to economize heat which resulted in a great saving of fuel, higher smelting temperatures, more

rapid working and a large increase in furnace output. This decline in the price of iron was one of the most important factors in the development of manufacturing. Minor improvements in processes were introduced by foreign manufacturers (the French use of furnace gases to heat steel, for example, introduced in 1811); but although iron production grew rapidly on the continent, the iron industry at this time was predominantly British, the basis of Britain's industrial supremacy and of its leadership as the workshop of the world. The industry received another tremendous impetus from the introduction of railroads in the 1830's, both because of their demand for iron and of the provision of cheaper and better transportation. Moreover the construction of railroads in economically backward countries increased Britain's exports of iron as well as the export of capital to finance construction of the railroads.

Meanwhile in the vast forests of North America the iron industry persisted in the use of charcoal for one hundred years after that fuel had become obsolete in England. By the middle of the eighteenth century the British colonies were producing almost as great a quantity of pig iron, bars and blooms as the mother country, perhaps from a fifth to a third of the world output during this stage of the charcoal era. England encouraged the colonial production of pig iron and discouraged the manufacture of iron, but there is no evidence that these tactics relieved the situation of the ironmasters in the mother country. After the War of Independence American production declined and the new country did not regain its relative position for a century. Production was mostly in the form of cast iron produced in small charcoal furnaces making from a few tons up to 25 tons per week. In contrast with the contemporary progress in Great Britain there was little improvement in American smelting practise between 1790 and the introduction of anthracite in the 1830's. As late as 1825 the use of mineral fuel was unknown, and the census of 1850 enumerated only 4 furnaces burning coke. Throughout the charcoal era the iron industry was a rural one; the furnaces and forges were scattered in every state in the union, although the establishments were more numerous in areas where surface outcroppings of ores were readily available.

In the United States the first great improvement in the production of iron came with the introduction of anthracite in smelting, first used in 1812 but not an important factor until

1840. The use of this peculiarly American fuel in smelting enabled the furnace stack to bear a much heavier burden of ore, flux and fuel than had been possible with the fragile charcoal. Anthracite iron maintained its ascendancy until after the Civil War. A thriving iron industry concentrated in the anthracite fields of eastern Pennsylvania with easily accessible markets. The introduction of anthracite prepared the expansion of the American iron industry, which was stimulated by the manufacture of solid iron rails and the rapid growth of railroad construction. Railroads absorbed from one third to one half of the iron output; the demand from other industries was still small because of the relatively slow pace of industrialization. English competition was keen and the American industry insisted that its existence depended upon high tariffs. Nevertheless, in 1850 approximately 60 percent of American iron needs were supplied by imports. Despite continuous tariff protection the American iron industry in the years 1850 to 1860 was still a poor second to the British industry, but the Civil War gave the American output an enormous stimulus.

In Germany the industry forged rapidly ahead after 1840, mainly as a result of the rapid growth of railroads and of a series of inventions which improved materially the quality of cast iron and made it in some respects superior to the British product. The rise in the output of German iron was interrupted by the world crisis of 1857, after which the development was resumed at a more rapid rate, stimulated by the increasing manufacture of improved ordnance by the Krupp works. In 1860 Germany produced 522,000 tons of pig iron in comparison with 821,000 tons produced in the United States and 3,890,000 tons in Great Britain. In France the industry was also expanding rapidly, although on a much smaller scale than in the other major producing countries. At the outbreak of the Franco-Prussian War the iron industries of both Germany and France had reached approximately their maximum development with the ores and technical practises then prevalent.

In 1870 Great Britain was still the world's leading producer of iron; it produced 5,964,000 tons of pig iron while the American output was 1,665,000 tons and the German 1,240,000 tons. As the figures in Table II indicate, the situation was completely changed within thirty years. In the decades between 1860 and 1890 the American iron and steel industry began to outstrip the other major producing countries. The Amer-

ican producers, competing among themselves for new records, embarked upon a spectacular campaign of furnace driving; the reports of mounting daily output per furnace were greeted with incredulity in England. During each of these decades the annual production of American pig iron doubled. The British output increased considerably during the same period, but it could not meet the pace set in the United States. By 1890 American production exceeded the British, and the United States became thereafter the leading producer of iron and steel. This phenomenal growth took place in spite of seemingly insuperable obstacles to the use of ores mined thousands of miles from coal, manufacturing facilities and markets.

At the basis of the increasing output of American iron and steel was the amazingly swift tempo of the country's industrialization. Horse power in manufacturing rose from 2,346,000 in 1869 to 5,939,000 in 1889 and 10,098,000 in 1899, this rise reflecting an enormous increase in the use of machinery. Railroad mileage rose from 30,626 in 1860 to 163,597 in 1890, an unparalleled growth which would have been impossible except for the advance of cheaper tonnage steel. The expanding agricultural machinery industry also required large amounts of iron and steel; and the output of metal consumption goods mounted steadily. These demands the iron and steel industry was able easily to meet because of its large reserves of coal and iron,

increasing integration and efficiency of operation and almost prohibitive tariff duties.

In Germany also the industry developed rapidly. In the ten years after the annexation of Alsace and Lorraine with their great stores of iron ores the German output of pig iron doubled and continued to increase almost as rapidly as in the United States. This growth reflected the general expansion of industry in Germany (including railroad development) and progressive specialization in the manufacture of iron and steel products, such as cutlery and ordnance. By 1910 the German output of pig iron exceeded the British—12,905,000 tons as against 10,012,000 tons. The easy economy of production in Britain, where adjacent raw materials, iron and steel mills and consuming industries had long formed a fortuitous union, had apparently reached the elastic limit of expansion. The world's pioneer iron and steel industry was now unable to compete on even terms with the resources and technique of the United States and central Europe; this was an important factor in the relative decline of British manufactures and the decline of Britain as the workshop of the world. Meanwhile the iron and steel industry had been developing rapidly in France, Belgium and Sweden. In 1913 the per capita consumption of iron and steel (in pounds) was: United States 600, Germany 575, Great Britain 520, Belgium 419, France 333, Sweden 333, Italy 84.

These changes in the relative position of the great producing nations were bound up with the change from iron to steel as the industry's major product with the introduction of the Bessemer steel making process. Prior to 1870 steel was not a tonnage factor in the industry. The metal of the early industrial revolution was iron, cast and wrought. Steel was a high grade special product, relatively expensive, used for cutlery and edge tools. Since early times steel had been made by the cementation process, a variety of what is now called case hardening whereby small bars of iron embedded in charcoal are heated for days until they are impregnated with carbon. The crucible process of later origin is closely related to the cementation process. Steel making was a small scale industry, less spectacular than iron making, although fine steel cutting tools have been essential in the technology of all times. Industry required a cheaper steel and this was first provided by the Bessemer process. The new steel was not as fine as the old, yet for most purposes better than cast or wrought iron. Although there is no

concise and satisfactory definition of steel, which always includes carbon but varies widely in its chemical composition, the term has come to be applied to all refined ferrous products aside from pig iron, cast iron, malleable cast iron and wrought iron.

The pneumatic method of making steel was discovered independently by an Englishman, Henry Bessemer, and an American, William Kelly, but Bessemer developed the process more fully and pioneered in making its commercial application possible. Bessemer's epoch making discoveries in England in 1855 and 1856 arose out of his quest for a material with the qualities of malleable iron to be used in the casting of cannon. By driving a blast of air through a bath of molten pig iron he oxidized the metalloids without the use of fuel and obtained a metal purer than ordinary cast iron; unfortunately, however, the phosphorus which remained in the resulting metal rendered it practically useless and the process could be used only with pig iron containing very small quantities of that element. The Bessemer process was consequently hampered by the limited supply of non-phosphoric ores both in Britain and elsewhere. It was therefore an event of major importance when Thomas and Gilchrist in 1879 successfully introduced an adaptation of the Bessemer converter which for the first time rendered phosphoric iron ores completely available for the manufacture of steel. A premium was actually put on the use of phosphoric ores for the slag was found to be a by-product highly prized as a

fertilizer. The Lorraine iron region with its phosphoric ores was now ready to come into its own, and the final technical obstacle to the uninhibited and phenomenal rise of the world iron and steel industry was removed.

Bessemer steel was destined to yield early precedence to the product of the regenerative open hearth furnace. In 1856 before the Bessemer converter was widely accepted William Siemens demonstrated that the use of gas to heat the furnace hearth produced high temperatures and fuel economy, the gas being developed by the burning of coal in auxiliary producers prior to its combustion in the furnace. This process slightly improved by the Martin brothers of France was in commercial operation by 1865. The advantages of the Siemens-Martin regenerative furnace over the Bessemer process are as follows: the use of ore as an oxidizing agent and the external application of heat render the temperature of the bath independent of the chemical reactions, which gradually eliminate the impurities in such a manner that the temperature and composition of the boiling metal are under more precise control; a larger diversity of products from a greater variety of raw materials may be produced; a greater output of finished steel is obtained from the same amount of pig iron, thus reducing the number of blast furnaces required in the industry; phosphorus can be eliminated from Bessemer ores even more satisfactorily than by the Thomas-Gilchrist process. In the United States this latter fact is of great importance since immense ore deposits are

rendered available which could not otherwise be utilized. The basic open hearth process has become the leading method in the United States and Great Britain; on the continent the Thomas converter is still used in refining most of the pig iron from the Lorraine deposits.

The statistics in Table III show not only the victory of open hearth over converter steel but also the enormous increase in the output of steel from 1870. The substitute for puddled iron resulted in an extremely rapid expansion of plant and of markets in the United States, England and other countries, as the new product offered a cheap, superior and plentiful supply of steel in a great variety of forms. The manufacture of wrought iron declined to the position of a minor branch of the industry. The Bessemer and open hearth processes laid the firm foundations of the modern steel age.

All finished iron and steel has once been pig iron, a semifinished material requiring further refinement before manufacture; hence the blast furnace is the common denominator of the iron and steel industries. There has been a revolution in scale and method of operation, in furnace design, in auxiliary equipment and in the economical use of raw materials, but the essential principles of the blast furnace have remained unchanged since the early furnaces. As the data in Table IV show, the productivity of blast furnaces has increased steadily and spectacularly, particularly in the United States. From 1740 to 1860 British furnaces were improved in efficiency by more than 200 percent and led all other nations in output. But British output was exceeded by American production in 1885 and by German production in 1890; since then Britain has fallen far behind the other leading producers in output per blast furnace. Improved smelting efficiency has lowered costs, consumption of coke and flux per ton have been reduced remarkably, and actual yields are more closely approaching theoretical yields even though the iron content of the available ores drops somewhat each year. Today the modern steelworks stack will make from 600 to 1000 tons in a single day with the same operating crew required by small furnaces, with a resulting large increase in the productivity of labor. According to estimates made by the writer average blast furnace crews in the United States have fluctuated within narrow limits since the 1880's, ranging from 116 men per furnace in 1884 to a high point of 185 men per furnace in 1908 and dropping again in recent years to a low

point of 121 men per furnace in 1929. Along with increased furnace output have come improvements in handling materials, until at present the electrically controlled stoking operations of modern furnaces are practically manless.

There have been equally great gains in productivity in the steelworks and rolling mills. The most far reaching change has been the rise of the continuous process whereby the steel furnaces receive hot metal directly from the blast furnaces, and the time formerly required for reheating is eliminated. As shown in Table V, 82 tons of finished steel per man were pro-

duced in 1899, about three times the productivity of 1880. By 1910 the output per man had risen to 111 tons and to a still higher level in 1915 and 1916, when American steel plants began heavy shipments to war ridden Europe. Productivity has since continued its upward march, reaching approximately 138 tons per man in 1929, probably five times the efficiency of fifty years ago. Hand charging of the open hearth furnace has disappeared; labor saving equipment in all modern operations is now substantially uniform from plant to plant. The tendency of the large producers is toward the construction of open hearths with a tonnage capacity ranging from 150 to 200 tons per heat. The modal furnace for the industry has a capacity of from 75 to 90 tons, with the same operating crews required regardless of the size of the furnace. Higher indirect costs for the larger furnaces are counterbalanced by lower tonnage costs. The progress over this entire period has been due to increasingly effective combustion control; the construction of ever larger furnaces; the combination and elimination of occupations, especially after the partial introduction of the 8-hour day in 1923; and the universal adoption of the standard labor saving devices, most of which were known as early as 1911.

Among the most important improvements yielding higher productivity are straight line production and automatic control, which have reached their highest development in the rolling of steel. After Cort's original application of steam power to the rolling mill manual labor was still indispensable in the handling of the metal as it passed to and fro in the rolls. The modern specialty mills making highly standardized shapes or products are usually continuous automatic mills with series rolls arranged in tandem, automatically handling the glowing metal as it is transformed from ingot to finished shape without reheating. The scale of operation required by this continuous process is typical of all modern plants in the industry. Reduction of costs in rolling mills has been made possible by the increasing standardization of shapes and chemical requirements. Steel rails are highly standardized, for example, while there is little uniformity in the steel requirements of the automobile companies. In the rolling mills arduous manual labor has been reduced to a minimum in recent years as a result of electrification and standardization. The electrification of main roll drives and incidental controls has facilitated smooth operation and has saved maintenance

and indirect labor. In 1905 there were only 5 electric main roll drives in the iron and steel industry in the United States, while in 1931 there were 1806 such installations, with an aggregate capacity of 3,000,000 horse power out of the industry's total rated horse power of not much more than twice this figure. These developments are factors in the increased output of finished steel per worker.

The spectacular increase in blast furnace output would have been impossible without the employment of the fibrous coke, which supports the burden of larger and taller furnaces without impeding the blast. Despite its economic advantages coke at first was slow in supplanting the use of anthracite in the American industry. It was not until 1875 that the total output of coke burning furnaces exceeded that of anthracite stacks, but since that time the growth of production and the increasing efficiency of smelting have been due in large part to the exclusive use of better and better metallurgical coke. Coke has been an important factor in the integration of the steel industry; the Carnegie company became dominant in the industry only after it acquired the Frick coking interests in 1882. The making of metallurgical coke is now the most important auxiliary of the steel industry. Historically iron ore is almost always brought to coal rather than coal to the ore. The continuance of this tradition is explained not solely by the importance of coke in the blast furnace but by the large quantities of coal and of coke oven gas required to supplement blast furnace gas in providing power for the integrated steel plant, which owns and controls its own coal mines and coking ovens. The production of coke has been improved by the slow but steady adoption of the distillation process. In the old beehive process all of the constituents of coal aside from the coke itself were wasted, while distillation now yields such valuable by-products as the benzols, toluol, naphthalene, tar and ammonia. From 1913 to 1931 the total American coke production (including domestic coke) increased from 12,700,000 tons to more than 32,000,000 tons, 70 to 80 percent of which was manufactured by distillation in by-product plants operated in connection with steel-works or merchant blast furnaces. To supply a modern furnace plant with coke a sufficient supply of gas is produced, in combination with blast furnace gas itself, to operate all of the heavy machinery of the mills with a surplus left over for the market. In addition to its financial

advantages the integrated operation of coke plants guarantees a steady supply of uniform coke for the smelters. Practically the entire output of coke is now produced by steelworks or public utilities engaged in the manufacture and sale of artificial gas. This type of integration is now universal in steel plant operation in all countries.

With the growth of the steel industry the isolated merchant blast furnace of small capacity has permanently declined in the United States. This decline has been due to the steadily falling price of pig iron, to the high comparative costs of small scale operation and to the ruinous competition from steelworks furnaces which in slack times dump surplus iron on the market. What remains of the merchant iron industry is chiefly dependent upon the foundry trade. Except as casting is required for the internal operations of the basic industry, the foundry is a distinct industrial entity with two main branches, the gray and malleable iron foundries and the steel foundries, and with two distinct types of business concerns, the jobbing foundries and those operated in conjunction with machining and fabricating enterprises. The jobbing foundries are physically dissociated from other processes; the trade is loose and decentralized, composed principally of small scale units producing and selling a wide variety of products for local use. The growing importance of steel melting units, usually larger than the iron foundries, reflects the inroads of steel into the domain of the gray iron casting.

Perhaps the most far reaching recent change in steel manufacturing was the introduction in 1927 of a remarkable process of continuous strip sheet rolling. Largely because of the expansion of the automotive industry the production of steel plates and sheets (including tin plate) increased until by 1930 it absorbed 30 percent of the total steel output. Since the early days in Wales the bulk of the product has been produced on simple hand rolls; to roll sheets by a continuous process without reheating was considered an impossibility. In the United States in 1929 there were roughly 1400 of the old mills in the sheet and tin plate industry, with an aggregate annual capacity of 7,500,000 gross tons of sheets. One of the new continuous strip sheet mills has a yearly capacity of approximately 400,000 gross tons of uniform gauge, equivalent to the capacity of forty or fifty old style sheet or tin mills. According to present indications the "hot mills" may

become as obsolete as the bloomery and the forge. More than 10,000 workers may be displaced when both direct and indirect labor items are taken into account, and sheet production will be concentrated in the hands of a few concerns. Hitherto the steel sheet trade with its growing market has attracted a large number of small independent concerns into a highly competitive industry not physically integrated with the central processes and requiring comparatively little capital. A series of recent mergers again demonstrates the dual role of technology and unfavorable market conditions in stimulating concentration. By 1931 the continuous strip sheet process was adopted by 9 American producers, including the United States Steel Corporation, and by a number of foreign producers.

Increased productivity in the basic iron and steel making processes and in the production of coke has been paralleled by similar progress in the mining of iron ores. Ore mining is an auxiliary of the iron and steel industry; in 1922, according to the Federal Trade Commission, two American steel companies owned or controlled over one half of the available reserves of iron ore. Average daily output per man in ore mining has increased steadily, rising from $3\frac{1}{2}$ tons in 1911 to 9 tons in 1929. Since the percentage of production from open pit mines has not materially changed, the explanation of improved efficiency must be sought in the operations of underground mines where mechanical slusher hoists have been extensively introduced, increasing shift production per man from 8 or 9 tons by the hand process to 15 or 18 tons with the new equipment.

In recent years there have been no marked technical advances in the American steel industry, which in comparison with many other industries is relatively backward in scientific research, devoting its attention primarily to the pursuit and consolidation of profits on the basis of past discoveries and inventions. Two interesting developments, however, have taken place in the manufacture of wrought iron and in the small scale production of sponge iron. Wrought iron has been displaced by the stronger Bessemer and open hearth steels, but the earlier product retains valuable physical properties because of its ropelike structure and its resistance to corrosion. The mechanical difficulties encountered in making wrought iron at low costs have been found in the puddling and not in the rolling processes, but now the Ashton mechanical puddling process has successfully produced in a

fraction of an hour an amount of wrought iron which from the time of Henry Cort had required a day's labor. Wrought iron still enjoys advantages in the manufacture of pipe, certain railroad accessories and other specialties, but it is not likely to become a serious competitor of tonnage steel. Recent experiments with direct methods of steel making have demonstrated that sponge iron can now be made directly from the ore without the introduction of impurities from the coke and flux of the blast furnace. This direct conversion is only practicable on a small scale at present, and its manufacture is too expensive for tonnage production; the new process can, however, readily provide iron for small concerns in outlying districts, where a large blast furnace would be impracticable, and it is effective in smelting ores not readily usable in the blast furnace.

More important is the recent growth of alloy steels in response to the increasingly exacting requirements of the steel trade. Alloys are useful especially in the manufacture of automobiles, airplanes, electrical machinery and other products which need steel of particularly fine quality. From 1925 to 1930 the alloy steels composed from 5 to 7 percent of the total American production of steel. The increasing production of fine steel is a counterinfluence against the development of extremely large furnaces and places a premium on the employment of highly skilled workers to supervise the necessarily careful operations in alloy production. Alloy steels are refined in the open hearth furnace or in the smaller electric furnace which replaces the costly crucible process for making finer steels and permits more precise control of temperatures and chemical reactions. In recent years the "electric" steels have provided between 1 and 2 percent of the total American production, but the figure obscures their real importance in the fine steel industry. One of the alloy products of the electric furnace is stainless steel, a combination of iron (customarily 74 percent), chromium and nickel. This alloy steel is practically impervious to rust, heat and acid and since 1927 has been improved and has assumed increasing importance. In 1931 the United States Steel Corporation purchased the rights to an improved method of manufacturing stainless steel perfected by the Friedrich Krupp A. G. of Germany, becoming the fourth American company to engage in the production of stainless steel. The price of the product is still very high, but increasing demand and vol-

ume production are expected to lower it materially. Alloys are not only providing a finer material for old products but are also opening up new uses for steel.

One of the important long time technical changes in the industry is the increased use of steel and iron scrap in steel making, as a result of which the annual output of steel now regularly exceeds the output of pig iron in all steel producing countries. In the United States in 1896 approximately 750,000 tons of scrap were remelted in making steel, in 1900 about 2,000,000 tons were used in this manner, and in 1929 the consumption of scrap reached the enormous total of 25,000,000 tons, about 45 percent of the total production of steel. If there were to be a scrap famine today, twice as many blast furnaces would be required to support the steel industry. The sources of the scrap metal are varied. It is estimated, for example, that the number of automobiles commercially scrapped has increased from about 794,000 in 1922 to 2,450,000 in 1928. The use of scrap supports a steel industry in areas where smelting is uneconomical and where freight rates for pig iron are prohibitive. It is not limited to the iron and steel industry itself; thus the Ford Motor Company provides much of its steel and foundry iron requirements by salvaging its own used cars on a large scale.

Technological and other changes in the iron and steel industry have been accompanied by increasing integration of operations and concentration of corporate control in all the producing countries. Concentration in iron and steel has advanced further and proceeded more rapidly than in any other manufacturing industry. The production of iron and steel has always required relatively large amounts of fixed capital; these were enormously increased by the technological transformation wrought by the industrial revolution and the subsequent integration of operations, which laid the physical basis for amalgamation and large scale combination. All developments since have emphasized the need of large fixed capital. In the United States the capital investment per wage earner in blast furnaces rose from \$6 in 1849 to \$150 in 1919, and in rolling mills and steelworks from \$30 to \$170. Since 1919 the investment has again greatly increased. The concentration arising from large investment of fixed capital and integration of operations has been supplemented by vertical and horizontal combination—by the ownership or control of sources of raw materials and of

transportation and by the diversification of output, including the manufacture of products not strictly within the domain of the heavy iron and steel industry. The concentration within the industry represents in an acute form the tendencies inherent in large scale production.

Adoption of the Bessemer process and the use of coke in smelting in the United States was accompanied by integration and concentration. In 1882 the Carnegie Steel Company acquired control of the H. C. Frick Coke Company, which dominated the Connellsville district of Pennsylvania; in 1897 it secured control of large Lake Superior ore reserves; by 1900 the company was entirely independent in its supply of raw materials and transportation facilities and manufactured a wide variety of products, including steel for naval vessels. The Carnegie profits were large—\$133,000,000 from 1875 to 1900, \$40,000,000 in 1900 alone, exclusive of reinvested profits. Stimulated by the sharp decline of prices and profits due to cut-throat competition and the depression of 1893-96, the industry put through a series of mergers which gave rise to a relatively small number of large companies. These companies fell into two definite classes, those which made pig iron, steel billets and other heavy products, and those which manufactured more highly finished materials. This movement toward consolidation had as its main objectives the restriction of competition, the physical integration of primary manufacturing processes (involving only the more standardized products), the control of raw materials and transportation and the flotation of securities in the expectation of large future profits. The chief of these objectives was the desire to limit competition, although the flotation of securities was most important to the promoters—at least \$150,000,000 in profits was realized by promoters in the series of mergers which culminated in the United States Steel Corporation. Despite mergers and concentration competition was still rampant by 1900 and threatened to flare up more disastrously. Companies manufacturing finished steel prepared to make their own crude steel, and the Carnegie Steel Company retaliated with plans to manufacture finished steel, build a competing railroad and wage ruthless competitive war. To forestall this threatened overexpansion and ruinous competition the Morgan interests organized the United States Steel Corporation in April, 1901. This great combination united most of the leading heavy producers with the principal concerns manufacturing finished steel

in the United States and comprised some twelve combinations (including the Carnegie Steel Company), which in their turn had been formed out of 200 or more independent enterprises. The corporation was heavily watered; a capitalization of \$1,384,000,000 was imposed on tangible property worth only \$676,000,000 according to the United States Bureau of Corporations. The water was subsequently squeezed out by the reinvestment of profits. At its inception the United States Steel Corporation controlled 45 percent of the blast furnace output, 65 percent of the crude steel and 51 percent of the finished steel production of the United States. With the exception of the purchase of the Tennessee Coal and Iron Company in 1907 the corporation has refrained from any major acquisition. This expansion and the corporation's restrictive influence in the industry led the federal government in 1911 to institute an action to dissolve it under the antitrust laws; in 1920 the United States Supreme Court decided the case against the government. The growth of the United States Steel Corporation has lagged behind the progress of the industry—its capacity declined from 65 percent of the total in 1901 to 40 percent in 1929. Other concerns, however, have integrated and combined. Between 1919 and 1929 no fewer than 270 mergers achieved consolidations among 690 individual concerns engaged in the manufacture of iron and steel and its products, while more than 1000 concerns totally disappeared. This expansion through mergers (and to a smaller degree extension of plant) has aimed at diversification of products, access to new markets and control of production and sales. In 1930 six great combinations controlled 75 percent of the industry's output in the United States.

Because of concentration and the reluctance of the United States Steel Corporation to affiliate with national groups, the American steel industry has not been fertile ground for the development of trade associations (which, however, flourish in the manufacture of metal products). The American Iron Association organized in 1855 was subsequently succeeded by the American Iron and Steel Association, which in 1911 became the American Iron and Steel Institute. The institute has been used to promote the stabilization of competitive practices and has provided a channel for discussion of business and technical problems and the compilation of trade statistics. A strong trade organization, the National Association of Flat Rolled Steel Manu-

facturers, has been organized among the independent sheet producers; and the Institute of Scrap Iron and Steel unites the ferrous scrap industry.

Under the influence of the United States Steel Corporation and because of increasing concentration among independents American steel production has been in a state of "monopolistic competition" in which prices and output are substantially controlled by a few cooperating producers. Beginning in 1907 there was an active effort to enforce a uniform price system by means of the informal Gary dinners, which were finally abandoned in 1911 as a result of widespread criticism. However, price stabilization was effectively supported by other means, particularly by the Pittsburgh-plus practise maintained under protection of the United States Steel Corporation—a practise whereby consumers were required to pay Pittsburgh base prices for steel plus the equivalent of the freight rates from Pittsburgh, regardless of the point of actual manufacture of the purchased steel and without reference to the costs of production in the various districts. After 1910 consumers of steel particularly in the middle west became restive under Pittsburgh-plus and in 1924 a group of associated western states secured a ruling from the Federal Trade Commission condemning the system "as an unfair method of competition" in violation of the federal laws prohibiting price discriminations. The subsequent breakdown of Pittsburgh-plus has given rise to a new multiple basing point system, but the leadership of Pittsburgh in the industry has been definitely impaired and an artificial barrier removed from the further development of the Chicago and Great Lakes districts as the natural economic centers of most efficient production and distribution.

In view of the huge fixed capital requirements of iron and steel manufacture the financing of the industry is more akin to that of railroads and public utilities than to that of the usual manufacturing enterprise. An analysis of financial ratios in various American industries has shown that steel ranked at the bottom of a list of eleven industries in the rate of turnover of fixed capital during the years 1914-21, showing a ratio of .7 as compared with approximately 3 for automobiles and 10 for slaughtering and meat packing. The larger companies ordinarily enjoy lower costs of production than the smaller concerns, but investigations have revealed that the larger enterprises generally

yield a smaller return on investment than is earned by the less thoroughly integrated firms in prosperous times. According to the Federal Trade Commission fourteen completely integrated steel companies had an average rate of return of 21.9 percent from 1915 to 1918, while the less integrated companies earned progressively higher rates, 42 rolling and finishing mills yielding an average rate of 36.8 percent on invested capital. Since most of the steel capacity is concentrated in the hands of the integrated companies, the industry is eager to stabilize prices and thus attain a secure and steady margin of profit above fixed and operating charges. Although a relatively high degree of price stability has been characteristic of the American steel market in recent years, there is no evidence that the achievement has increased the stability of production or employment.

Although the British iron industry was one of relatively high integration and concentration during and after the industrial revolution, it lagged behind the onward sweep of concentration after the introduction of the Bessemer and open hearth processes. This was due to the conservatism and independence characteristic of old family concerns with strongly developed pride of ownership and to the general relative decline of British industry after 1890. These influences inhibited the combination movement and hampered the efficiency of the industry, yet both vertical and horizontal combinations have been more extensively developed in iron and steel than in other British industries. In 1919, 30 companies controlled 80 percent of the iron and steel output. During and since the World War there has been a rapid extension of large plants in Britain and, although the physical make up of the industry continues to reflect the conservatism of earlier days, integration and concentration have considerably increased. Vickers, Ltd., have greatly enlarged the scope of their operations by means of mergers and new plant. In 1929 Bolckow, Vaughan and Company, Ltd., merged with Gorman, Long and Company, Ltd., and the new concern acquired control of four other companies; in addition it owns one half the share capital of five other companies, two of which are in South Africa. The Bolckow-Vaughan company has an annual capacity of 2,500,000 tons of steel ingots and 4,000,000 tons of coal. Most of the iron and steel companies own their own coal and iron mines; in 1925 it was estimated that they owned one fifth of the coal mines in Great Britain. Diversification of

output is increasing along with concentration and rationalization. The industry is still strongly competitive, however. British steel manufacturers are now closely banded together in the strong National Association of Iron and Steel Manufacturers organized in 1918 at the suggestion of the government; in 1932 it extended its membership to include representatives of the iron and steel industries of the empire.

The iron and steel industry in France is much less competitive than in Great Britain; integration and concentration are more highly developed, but they lag considerably behind the United States. Where there had been more than 1000 French metal works in 1864, integration and combination reduced the number to 208 in 1912. Competition was never really very active because of the work of the *comptoirs*, a form of cartel or unified selling agency, although these never had the extensive control of the American trusts or German cartels. The strong Comité des Forges, founded in 1864, has the legal status of an employers' association with no right to transact business, yet it has been the most active central influence in the industry, fostering the pre-war iron and steel cartels and exercising unified administrative authority over the entire metallurgical industry during the World War. *Comptoirs* began to appear at an early date in France. There was one for pig iron as early as 1876; in 1904 a *comptoir* for the export of metal products and in 1905 one for the export of pig iron were set up. During the war the *comptoirs* disappeared and efforts to revive some of them have been unsuccessful. But in their place integration has made considerable progress, especially vertical organization including all stages of production and distribution. These organizations tend to expand and absorb an increasing proportion of the blast furnace output. Horizontal combinations have not been important except in Lorraine, where five groups of associated companies acquired control of the former German iron and steel concern. This is an outstanding example of concentration, since the Lorraine enterprises now constitute the basis of the French industry. The major French producers have a diversified output, including the production of munitions.

Integration of operations and concentration of corporate control are more highly developed in Germany than in any other European country, almost as highly developed as in the United States. This was true also before the World War, although partly obscured by the prevalence of

cartels. The Krupps early adopted a policy of integration and diversification, which has been maintained; they acquired ownership or control of coal and iron mines as well as transportation facilities (including a fleet of ships to carry ores from Spain), combining all stages in the manufacture of a variety of products—many of them more within the scope of the metal or engineering industries—and in 1896 went into shipbuilding. During the post-war inflation period Hugo Stinnes formed a huge iron and steel combine, which disintegrated after his death and the restoration of a normal currency. Rationalization stimulated the movement of integration and concentration, which culminated in 1926 in the formation of the United Steel Works (Vereinigte Stahlwerke A. G.), a consolidation of the Rhein-Elbe Union, formerly in the Stinnes combine; the Thyssen and Phönix groups; and the Rheinische Stahlwerke A. G. The new combination had 40 percent of the German industry's capacity and it was increased in 1932 by absorption of the principal iron and steel works of central Germany; in 1929 the United Steel Works had assets of 2,145,000,000 marks and owned a large block of stock in one of the most important manufactories of machinery. Within recent years six giant concerns have dominated the industry, their combined quotas in the cartels ranging from 55 percent in pig iron to 91 percent in plate. Cartels, partly a substitute for and partly a supplement to integration and concentration, flourished in Germany as early as the 1860's. Before the World War there were two main cartels—the pig iron cartel (Roheisenverband) and the steel cartel (Stahlwerksverband), the latter uniting 10 subsidiary cartels of manufacturers of semifinished products. All cartels except the pig iron were dissolved during the post-war inflation period, but many including the steel cartel have been subsequently revived. Since 1924 the raw steel syndicate (Rohstahlgemeinschaft) uniting companies, including Krupp, which could not or would not join the steel cartel, has imposed production quotas upon its members, although it does not allocate orders and sales or fix prices. There are a number of other cartels in the industry.

An extremely high degree of integration and concentration has characterized the iron and steel industry of Russia since the acceleration of the industrial evolution of that country after 1870. Before the World War there were several huge steel plants, such as the Pugachev Works in the Donets basin, each of which employed

over 10,000 workers. Soviet Russia, particularly since the adoption of the first Five-Year Plan, has concentrated on the building of an iron and steel industry as the indispensable basis of industrialization and consequently of the realization of socialism. The number of active blast furnaces increased from 45 in 1925 to 77 in 1929 and 92 in 1931; a total of 26 new blast furnaces, 65 open hearth furnaces, 7 electric furnaces and 27 rolling mills will be put in operation in 1932. A high degree of integration prevails in the iron and steel industry built up in the Soviet Union. The Ural-Kuznets combination of plants is to produce 6,500,000 tons of pig iron in 1933; 4,000,000 tons of Kuznets coal is to be transported 1400 miles by rail for the use of the Magnitogorsk steel plant, which rivals in size the American works at Gary, and on the return trip the cars will carry ores from Magneto Mountain to the secondary metallurgical base at Kuznets. The union's planned output of iron and steel in 1932 was placed at 9,500,000 tons, double the pre-war production. In Soviet Russia of course the iron and steel industry operates like the other industries under government direction and control. No other government participates directly in the industry except the German government, which in 1932 purchased a large block of stock in the United Steel Works.

In the capitalist countries the growth of integration and concentration has resulted in increasing control of the iron and steel industry by financial capitalists and the great banks. Steel stocks are ordinarily widely held; the multiplication of stockholders separates ownership and management; and control can be exercised by concentration of blocks of minority holdings in the hands of financial capitalists or banks or a combination of both. This control is unified and strengthened by means of interlocking directorates. Thus the United States Steel Corporation since its inception has been under the control of J. P. Morgan and Company, and most of the other large companies are in a similar position. In view of the industry's great capital requirements strong banking connections are indispensable. The general situation is the same in France and Germany. For example, the important French bank, Banque de l'Union Parisienne (which is closely allied with Schneider et Cie), has holdings in the important Longwy iron and steel companies and several other companies and finances the dominant group of Lorraine iron and steel producers.

In Germany the large D banks are represented on the boards of directors of all the important iron and steel companies; the Deutsche Bank was active in the formation of the United Steel Works and two minor combinations, while the Disconto-Gesellschaft, the most important iron and steel bank (now merged with the Deutsche Bank), has engaged aggressively in the trustification of the industry. In this fusion of large scale industry and finance the iron and steel industry is once more typical of the modern development of capitalist enterprise. Here again, however, Great Britain lags behind, although recent mergers and consolidations are producing conditions of financial control similar to that in other major producing countries.

Although Japan is developing its own heavy industry (stimulated by the World War but hampered by lack of raw materials) and there is one giant integrated plant in India, iron and steel constitute an essentially European and American industry. In the principal producing countries the industry has expanded greatly since the war, particularly in capacity, but only in the United States has there been any

considerable increase in per capita consumption (see Table VI), explained primarily by the unusual expansion in the American output of automobiles, machinery and metal products and in building activity. Italy's increase in 1925 was fortuitous; its post-war consumption was only slightly higher than pre-war. Great Britain's consumption was approximately stationary, while Germany's declined considerably. French consumption increased mainly because of reparations and acquisition of the Lorraine iron and steel industry, which temporarily stimulated industrialization. These developments express the

relative economic decline and crisis in Europe. The consumption of iron and steel rose only slightly among the non-producing countries. In 1929 the combined exports of Great Britain, the United States, Germany and France were 16,563,000 tons, a slight increase as compared with 14,698,000 in 1913; but the average for 1920-28 was slightly below the 1913 level.

The world's uneven rate of iron consumption and distribution of iron ores may result in important geographical shifts of the iron and steel industry in the immediate future. Knowledge regarding the amount and distribution of the world's ore resources (Table VII) is es-

...ion of the Lorraine iron and steel plants; while domestic consumption has risen considerably, mainly because of an accelerated rate of industrialization, exports are of ever increasing importance to France. England and particularly Germany have likewise increased their production capacity, while the growth of home markets has been restricted by national economic crisis and decline. According to a 1928 estimate, Belgium and Luxemburg must export 60 to 75 percent of their iron and steel output, France 40 to 50 percent of its output, and Great Britain and Germany 20 to 35 percent of theirs. Excess capacity and the desirability of continuous operation have forced down prices and profit margins and competition for world markets has been increased in consequence.

Because non-producing countries are not increasing their demands, the iron and steel exports of the world's leading producers in recent years have risen only slightly over those of 1913 (see Table IX on p. 314). The pre-war trend of American exports of iron and steel was distinctly upward; and although the post-war tendencies are somewhat confused, the trend since the Armistice has clearly been downward despite increasing capacity and the need for export markets. The position of the United States in the world trade in these products can be considered without reference to imports, which have remained practically constant for thirty years. American reliance on foreign trade in steel was stimulated by the abnormal wartime activities of the industry, and the aftermath of the war, which placed a premium on domestic production

years, and the total reserves of three times that amount should last for 1300 years if the world rate of production from 1926 to 1930 is maintained. New explorations hold promise of future increases in estimated reserves, but it must be remembered that geological availability is very different from commercial availability. According to present estimates the United States is richest in iron ores, with 41.8 percent of the world's total. The steel empire of the northern American states now rests solidly upon the unparalleled economy of the Lake Superior region, where the soft Mesabi ores of practically all grades are scooped by steam shovels directly into railroad cars, from which they are loaded by gravity into the ore boats of the Great Lakes. The reserves of this region are known to contain about 2,650,000,000 tons, most of which averages 55 to 60 percent iron; Kuhn estimates that the total possible reserves aggregate about 72,000,000,000 tons. Approximately one half of the Mesabi reserves are holdings of the United States Steel Corporation. Since 1910 Mesabi ores have provided more than half of the annual American output of 40,000,000 to 70,000,000 tons. In close proximity to coal and flux, the available Alabama ores are leaner but the known supplies are more extensive at present than the Lake Superior ores. The southern states contain known reserves of about 4,000,000,000 and possible reserves of about 10,710,000,000 tons. It is predicted by competent authorities that the high grade ores of the Mesabi region may be exhausted in about 30 years at the present rate of production and that the United States will begin to use large supplies of imported iron ores between 1945 and 1950. The American industry has already imported a small amount of ore—3,139,000 tons in 1929—the chief importer being the Bethlehem Steel Corporation, which because of its late entrance into the producing field was forced to go to Chile for the bulk of its iron reserves.

The large reserves widely distributed in Great Britain are ordinarily so lean that they require beneficiation before smelting; and for many years Britain has imported iron ores from various parts of the world, a fact which accounts in part for the backward state of its iron and steel industry. Germany's reserves were greatly reduced by the loss of the Lorraine ore fields in the World War, from which it must now import ores, while the French position has been correspondingly improved, with France now enjoying virtual monopoly of the iron mining industry

of western Europe. The Lorraine field, which yields from 30,000,000 to 40,000,000 tons annually, is the largest iron ore district in Europe and is estimated to contain over 6,000,000,000 tons of ore with an iron content of 25 to 48 percent. As in the Mesabi Range most of the Lorraine ore is mined by steam shovels directly from open pits. Large Spanish reserves exploited for more than two thousand years furnish valuable Bessemer ores for export to the iron and steel industries of other countries. In Soviet Russia the iron reserves are still largely unexplored and consequently seriously underestimated, as recent discoveries indicate; they include important deposits of rich ores at Krivoy Rog and Kerch in southern Russia and other ores in central Russia, the Caucasus and the Ural Mountains, with probable undiscovered reserves in Siberia. Contradictory to previous opinion in many quarters a recent survey in China indicates that the relatively small reserves of less than 1,000,000,000 tons of iron ore in that country cannot be regarded as a storehouse of future supplies.

While only Great Britain and Germany import ores to any considerable extent, all iron and steel producing countries must import a variety of commodities necessary in the fabrication of steel. The United States imports 40 of these commodities (one of the most important being manganese) from 57 different countries. The other producers are in a comparable situation. Most of the imported commodities come from colonial and other economically backward countries and constitute an important consideration in the politics of the imperialist powers.

Changes in the available reserves of iron ore as well as in the tempo of general industrialization have affected the relative distribution of the world's output of iron and steel between the leading producing countries. As indicated in Table VIII the expansion of the American share from less than 20 percent before 1880 to nearly 50 percent in the period 1921-30 contrasts sharply with the declining share of Great Britain, which in 1926-30 produced only 7 percent of the world's output compared with 50 percent before 1870. The solid position of central Europe (Germany, France, Belgium, Luxemburg and the Saar) is evident in the consistent progress of this region despite the bitter industrial and national rivalries which have hampered normal industrial operations. Central Europe on the whole has maintained its relative position; Great Britain's relative loss has been absorbed by the

United States. Within central Europe, however, important national changes have taken place with the reconquest by France of Alsace-Lorraine. Germany is no longer dominant in European iron and steel production, while the French industry greatly exceeds its pre-war proportions.

The international competitive situation in the iron and steel industry is influenced not only by ore reserves and the output of the industry but also by the problem of excess capacity as determined by available home and foreign markets. Since the World War this problem has become acute in all the producing countries (except the Soviet Union), the result of new plant, higher productivity and the restriction of markets. American capacity has increased more than domestic demand; in the case of the United States Steel Corporation capacity rose from 22,700,000 tons in 1920 to 26,075,000 tons in 1930. It has been estimated that despite the great increase in consumption the American industry must rely upon foreign markets to absorb more than 25 percent of its annual output, largely in the form of finished steel and highly manufactured products, as compared with only 12 percent in 1905 and approximately the same in earlier years. For semifinished products the need of export markets is somewhat smaller. The export of crude steel in recent years has ranged from 7.8 percent of the total output in 1922 to 4.1 percent in 1931. The capacity of European producers also has increased greatly in recent years. The French industry has augmented its capacity both by higher productivity and by ac-

quisition of the Lorraine iron and steel plants; and while domestic consumption has risen considerably, mainly because of an accelerated pace of industrialization, exports are of ever greater importance to France. England and particularly Germany have likewise increased their capacity, while the growth of home markets has been restricted by national economic crisis and decline. According to a 1928 estimate, Belgium and Luxemburg must export 60 to 75 percent of their iron and steel output, France 40 to 60 percent of its output, and Great Britain and Germany 20 to 35 percent of theirs. Excess capacity and the desirability of continuous operation have forced down prices and profit margins and competition for world markets has been increased in consequence.

Because non-producing countries are not increasing their demands, the iron and steel exports of the world's leading producers in recent years have risen only slightly over those of 1913 (see Table IX on p. 314). The pre-war trend of American exports of iron and steel was distinctly upward; and although the post-war tendencies are somewhat confused, the trend since the Armistice has clearly been downward despite increasing capacity and the need for export markets. The position of the United States in the world trade in these products can be considered without reference to imports, which have remained practically constant for thirty years. American reliance on foreign trade in steel was stimulated by the abnormal wartime activities in the industry, and the aftermath of the war, which placed a premium on domestic production

in the demoralized countries of Europe, left the United States unable to export the excess over normal domestic requirements. Germany exports about the same percentage as in 1913, but the total has shrunk considerably, while the exports of France have increased absolutely and relatively. The most serious decline is in British exports; the export of iron and steel continues to be much more vital to Great Britain than to the other major producing countries. Competition for foreign markets is aggravated by bounties and rising tariff barriers, including the British tariffs imposed in 1932 in the form of continuing tariffs on certain finished products and temporary duties on certain semifinished products. In the case of the United States the tariff on tonnage steel is now an anachronism, useful only in the protection of seaboard merchant iron producers, in fostering certain of the alloy steels and as an aid in maintaining stability of prices, particularly in the manufacture of specialty products such as tin plate.

Intensified competition for export markets has led in Europe to revivals of international cartels, such as prevailed before the World War. In 1926 an International Steel Entente was formed by the producers of Germany, France, Luxemburg, the Saar and Belgium. Czechoslovakia, Austria and Hungary subsequently joined the cartel. This agreement, scheduled to expire in 1931, proposed to adjust production to demand and to reorganize the market in central and western Europe. The terms of the cartel and the subsequent movement of prices furnish ample evidence that a price agreement underlay

the quotas arranged. The cartel has brought some degree of amity into the politically disunited industry, but its operations have been fraught with great difficulty, particularly in the allocation and enforcement of production and market quotas within the several countries. During 1931 and 1932 negotiations for the renewal of the cartel were delayed by the failure to agree upon quotas. On the other hand, some such international arrangement seems inevitable if the politically disunited industry is to function effectively. Cartels have been formed also among the continental tube, strip and wire industries. In Germany a movement has developed to curb the cartels on the ground that they maintain higher prices in the domestic market and lower prices in the export markets. The cartels answer that lower export prices are to secure foreign markets, and that exports by increasing output make domestic prices lower than they would be otherwise. Domestic attacks on international cartels have aggravated the instability resulting from the efforts of rival national producers to secure larger quotas.

The iron and steel industry has now reached comparative maturity. It seems unlikely that aluminum or any other metal will in the predictable future replace steel in its heavy uses; an iron and steel industry on approximately its present scale is indispensable for the maintenance and growth of material civilization under the conditions of technology now prevailing. The market, however, no longer expands as it did from 1870 to 1900, and production in recent years has remained relatively constant.

Meanwhile centralized organization, integration and concentration, a substantial degree of co-operative action and the availability of comprehensive trade information provide the managements of steel companies with an unusually adequate basis for effective planning. In addition to internal problems of organization and production there are two important international problems—the intensification of competition for export markets and the control and distribution of the raw materials scattered all over the world. What developments the future will bring in this vital industry is a matter of the utmost concern to every national community as well as to the society of nations.

MEREDITH GIVENS

LABOR CONDITIONS. *United States.* The largeness of capital units, the necessity of continuous processing in basic operations and the extensive mechanization characteristic of iron and steel production have been dominant factors in determining the status of labor in the industry. Labor is mainly unskilled or semi-skilled; hours are unusually long and the work arduous; and unionism has been effectively resisted by the giant corporations. In 1930 four large companies employed an overwhelming majority of the 577,000 iron and steel workers; nearly one half were employed by the United States Steel Corporation. The existence of large immigrant groups has complicated the work of organization, and craft separatism has played an important role in retarding unionism.

Although lifting and conveying machinery tended by "control workers" has largely replaced brawn in furnace operation, many unskilled workers, frequently recruited from immigrant groups, are still required for repairs, replacements and handling of materials. Many jobs involving high skill especially in heating processes have been abolished through technical changes. While the tasks of steel workers are not in general as monotonous as assembly work, except perhaps in the finishing trades, many men must labor in dirty, hot, drafty surroundings. The melting process involves an alternation of periods of intense activity and periods of less arduous work. Despite relatively high full time weekly earnings living conditions dominated by the long day or by irregularity of employment have been extremely poor. In many steel centers special problems have arisen in conjunction with the company town.

When the industry was first established in

America it used charcoal for fuel and was consequently localized in rural sections. Indentured Scottish prisoners taken by Cromwell, slaves, convicts and redemptioners were employed at various times and places. Skilled workers of the Saugus Iron Works of Massachusetts, established in 1643, were generally paid 2½ shillings (\$.42) a day plus board valued at \$.94 a week. At the Stiegel furnaces in Pennsylvania in the first half of the eighteenth century prevailing daily rates were 1½ and 2 shillings (\$.19 and \$.266) and board. In 1795 South Carolina steel workers received the value of \$9.00 to \$11.90 a month in bar iron or castings, from which \$4.50 was deducted for board. A Treasury report in 1832 estimated average daily pay at \$1.00, with more highly skilled men in New York and Connecticut receiving \$2.00.

The trend of wages in recent years, as shown in Table I, indicates an increase of 35 percent in real wages between 1890-99 and 1926, most of the increase appearing during the World War.

TABLE I
EARNINGS OF IRON AND STEEL WORKERS IN THE UNITED STATES, 1890-1926

| YEAR | AVERAGE ANNUAL MONEY EARNINGS | INDEX OF REAL EARNINGS (1890-99 = 100) |
|------|-------------------------------|--|
| 1890 | \$ 550 | 103 |
| 1900 | 567 | 104 |
| 1910 | 697 | 106 |

Between 1926, when the level was slightly below that of 1920, and March 31, 1931, hourly rates and full time weekly earnings turned slightly upward, the former rising from \$.637 to \$.663, the latter from \$34.41 to \$34.58. Wage cuts in 1931 and 1932 substantially reduced both rates. Rates for unskilled labor working a 10-hour day in United States Steel Corporation plants rose from \$2.00 in 1915 to \$5.06 in 1919. A series of reductions had brought the figure to \$3.00 in August, 1922. A rate of \$4.40 established in August, 1923, was continued for eight years. In the fall of 1931 a reduction of 10 percent was made; in May, 1932, another of 15 percent. Estimated full time earnings in 1931

for different branches of the industry are shown in Table II.

Source: *Monthly Labor Review*, vol. xxxiii (1931) 1184 and 1447-48, and vol. xxxiv (1932) 145.

Technical improvements and in the last few years speed up methods displaced considerable steel labor prior to the 1930 crisis. Between 1926 and 1928, when production advanced about 7 percent, employment dropped 9.1 percent and actual pay rolls 7.3 percent. In 1930 employment was 15.5 and pay rolls were 20.2 percent below the 1926 level; in 1932 both were considerably lower. Employment in Pennsylvania, where about one third of the industry is located, was in March, 1932, about 25 percent below the figures for January, 1931, while pay rolls were more than 40 percent lower.

Hours, especially in the continuous processes, have always been long; marked reductions date only from 1922 and the change is still far from complete. In 1913 full time blast furnace workers in plants surveyed by the United States Bureau of Labor Statistics averaged 76.9 hours a week. This total was gradually reduced until in 1922 it reached 72.3. After an abrupt drop to 59.7 in 1924 it rose slightly but in 1931 receded to 57.2. The average hours of full time Bessemer converter workers dropped from 70 in 1913 to 53.3 in 1931, while those of open hearth furnace workers fell from 76.7 to 53.8. Beginning in 1919 public sentiment against the 12-hour day and 7-day week increased and was crystallized in part by the publications of the Inter-Church World Movement, the Federated American Engineering Societies and the Federal Council of Churches of Christ in America. Although in 1924 the American Iron and Steel Institute, an organization of steel manufacturers, was forced by this sentiment to promise the

gradual elimination of these conditions, they still exist for a considerable percentage of workers especially in basic processes. The study by Hartl and Ernst indicates that of 300,000 steel workers surveyed in 1929 more than half were working 10 hours or more a day and more than a quarter were on a 7-day week basis, which "remains the heaviest burden on the workers in the steel industry." Maintenance crews have lagged most in effecting a reduction of working hours.

According to the United States Bureau of Labor Statistics accidents in the iron and steel industry have declined materially since 1907 (Table III). In that year workers were killed or injured at the rate of 80.8 for every million man hours of exposure (frequency rate), and for every thousand man hours of exposure 7.2 days were lost as a result of accidents (severity rate). In 1930 the frequency rate had been reduced to 18.6, a decrease of 77 percent, and the severity rate to 2.5, a decrease of 65.3 percent."

TABLE III

ACCIDENT RATES IN IRON AND STEEL IN THE UNITED STATES, 1907-11 AND 1926-30

| DEPARTMENT | FREQUENCY RATE (PER 1,000,000 MAN HOURS) | | SEVERITY RATE (PER 1000 MAN HOURS) | |

Source: *Monthly Labor Review*, vol. xxxiii (1931) 1035.

The bureau reports that in a selected group of plants where safety work has been stressed the reduction in accident frequency since 1913 has been 87.2 percent as against 15 percent for plants in which such work has not been emphasized.

Many iron and steel workers are subjected to wide and rapid variations of temperature. United States Public Health reports show that pneumonia occurs at almost twice the frequency among such workers as it does among those in a group of miscellaneous industries. The effect of radiant furnace energy upon health has been studied, but conclusions of such research are of uncertain value because of the probability that

workers continuing in these trades have superior physique and are more likely to resist disease.

Leaders in the steel industry, wielding arbitrary authority over a large number of unskilled workers, have not chosen to be innovators in welfare work, except possibly in safety work. The United States Steel Corporation was one of the first large companies to launch a plan of stock sales to employees. On December 31, 1926, after twenty-three years of sales, 47,647 employees were reported to own 163,802 shares of its preferred stock and 501,999 of its common stock. The plan has not resulted in transferring any control to labor, and in the long market decline beginning in 1929 many of the employees' stockholdings were wiped out. Housing and recreational programs have been developed by the United States Steel Corporation, especially for skilled workers. Pensions have been established out of a fund created jointly by Carnegie and the corporation. A considerable number of workers, chiefly in the Bethlehem Steel Company and the Colorado Fuel and Iron Company, have been given "employee representation," otherwise known as the company union. The workers are frequently afraid to bring important grievances before their "representatives" or the latter are afraid to fight for them. Wage cuts are often readily endorsed by company unions on the grounds that they cannot expect more than is paid by the largest industrial unit, the United States Steel Corporation, which is an open shop.

As in other countries the metal workers of the United States were early among the most advanced elements of the working class. They organized with vigor and persistence, experimented boldly and conducted many important and successful strikes. But with the displacement of many skilled workers by technical developments and with the failure of the unions to abandon with sufficient rapidity their craft basis unionism ceased to be a power. American steel corporations increasingly hostile toward labor organizations have used violence, spy systems, political pressure and economic controls to resist even conservative trade unionism. The industry was being organized into ever stronger units capable of putting up a hard fight against organization by the workers. Once unionism was broken in the leading plants it was doomed throughout the industry, and today less than 5 percent of the workers are organized.

The United Sons of Vulcan, the union of skilled iron puddlers organized in 1858 to resist

wage reductions following the panic of 1857, won in 1864 a sliding scale wage agreement based on the price of pig iron. In 1866 it wrote the first national agreement in American history and seven years later its membership reached a peak of 3331. In 1876 it joined with the Associated Brotherhood of Rail Heaters of the United States (founded in 1861 and later known as the Associated Brotherhood of Iron and Steel Heaters, Rollers and Roughers) and the Iron and Steel Roll Hands Union (founded in 1870), organizations of skilled workers, to form the Amalgamated Association of Iron and Steel Workers of the United States with 3000 members. Skilled tin workers were admitted in 1881. By 1891 the Amalgamated included 24,068 workers, about one quarter of those eligible, and had become a most powerful union. Its strongholds were the Pittsburgh and Youngstown districts, especially the iron mills, where as late as 1889 it was able to dominate the wage negotiations with employers. Because of the constant introduction of new processes, however, agreements with manufacturers were unstable and increasingly difficult to reach. Moreover in the 1880's the Knights of Labor challenged the power of the Amalgamated through National District Assembly 217, Iron, Steel and Blast Furnacemen, especially by taking in the unskilled workers barred from the Amalgamated. This threat soon died, but jurisdictional friction was rife among craft groups in the Amalgamated. Puddlers, roll turners, tin plate and rod mill workers successively threatened secession and some elements split off. In the Homestead strike of 1892 Andrew Carnegie and H. C. Frick employed private detectives and the state militia in a bitter union breaking campaign; as a consequence the Amalgamated lost control of the Carnegie shops and began to decline rapidly. In August, 1901, it made a vigorous but unsuccessful attempt to unionize workers of the hostile United States Steel Corporation and as a result lost its agreement with three of the corporation's large constituent companies. Minor strikes at McKees Rocks in 1909, Bethlehem in 1910 and Youngstown in 1916 were likewise unsuccessful. After 1910 insurgent movements led by the Industrial Workers of the World both within and without the organization helped to democratize the Amalgamated and in 1911 unskilled workers were nominally admitted to membership. The organization continued to seek out only the skilled workers, however, and in strikes of 1909 and 1919, in the latter case aided by several al-

lies, it was defeated by the fierce opposition of giant corporations.

An attempt to organize steel workers on a broad basis was launched on September 22, 1919, by a National Committee for Organizing Iron and Steel Workers. Led by William Z. Foster, it was backed at the outset by the American Federation of Labor and by twenty-four co-operating unions with jurisdictional rights in the industry. According to the union estimate 365,000 workers were brought on strike by an intensive campaign. Their demands were: the right of collective bargaining, the 8-hour day, one day's rest in seven, wage increases "sufficient to guarantee American standards of living," double pay for overtime and Sunday and holiday work, seniority, abolition of physical examination of applicants for employment and reinstatement of those discharged for union activity. The strike was met by a campaign of terrorism conducted by burgesses, magistrates, police and constabulary. Gangs of Negro strike breakers were imported from the south. The failure of the strike in December, 1919, was due not only to the terrorism but also to lack of coordination arising from the weakness of the craft structure, to the action of the steel companies in raising wages and allowing overtime pay in the months just preceding the strike call, to a "Red" scare initiated by the press, to the ability of highly integrated companies to shift production to areas in which the walkout was not fully effective and to the failure of the American Federation of Labor to stand by at critical junctures.

Largely by sufferance of a few employers the Amalgamated lingers as a conservative relic with a declining membership in wrought iron and a few sheet, plate and bar mills. Its jurisdiction is challenged by the Metal Workers' Industrial League, an affiliate of the Trade Union Unity League, which is attempting to organize the steel industry as part of the campaign to unionize the unorganized basic industries.

COLSTON E. WARNE

Other Countries. Because of the tendency to concentrate in certain relatively restricted areas and the general similarity of the processes involved, there is less variation from country to country in labor conditions in the iron and steel industry, including blast furnaces, steel works and rolling mills, than in many other industries. While American and European wages differ markedly, wages and hours in European

countries tend to move together since the large producing areas depend on export markets for their very existence; 20 to 75 percent of their output must be exported to utilize capacity fully. At the same time many important differences exist, and nowhere more than in the field of labor organization.

THE NUMBER OF WAGE EARNERS EMPLOYED IN THE IRON AND STEEL INDUSTRY IN THE PRINCIPAL PRODUCING COUNTRIES*

| COUNTRY | YEAR | WAGE EARNERS (in thousands) |
|---------------|---------|--------------------------------|
| United States | 1930 | 577 |
| Great Britain | 1929 | 252 |
| U. S. S. R. | 1929 | 202 |
| Germany | 1925 | 139 |
| France | 1926 | 114 |
| Belgium | 1926 | 40 |
| India | 1929-30 | 29 |
| Sweden | 1925 | 25 |
| Spain | 1924 | 21 |
| Luxemburg | 1930 | 17 |
| Canada | 1929 | 11 |

* Although care has been taken to include all wage earners employed in blast furnaces, steelworks and rolling mills and no other workers, differences in classification may render the figures not strictly comparable.

In the leading iron and steel countries, which together produced 86 percent of the world's pig iron and raw steel in 1930, more than 1,425,000 wage earners are normally employed in the industry. This is a minimum estimate; for Belgium, Sweden, Spain, Luxemburg and Canada the number of workers is probably underestimated. Since 1929 because of the depression the trend of employment has been seriously downward in all countries except the Soviet Union, where reports as of January, 1931, show an increase to 230,300 workers. The number employed in the Soviet Union has apparently

approached the number employed in Great Britain, where the figures compiled for July, 1931, from the live registers of the employment exchanges showed a total of 239,410 wage earners in the iron and steel industry.

Up to the time of the World War it was customary for iron and steel workers on continuous processes to work the two-shift system, which has now given way to the three-shift system in all the countries. The bulk of the British blast furnaces have been on three shifts since 1898, as have at least two British open hearth plants since 1905. The rest of the British industry adopted three shifts in 1919. Germany adopted three shifts in the immediate post-war period, but after the Ruhr occupation the employers were permitted to reintroduce the two shifts in order to recoup their finances; in 1925 and 1927 official decrees restored the three-shift system. Luxemburg legally adopted the 8-hour day in 1918. The decree introducing the three-shift system into the French industry was promulgated in 1920, and Belgium followed the next year. In India the great plant of the Tata Iron and Steel Company at Jamshedpur, which opened six years before the war on a three-shift basis, still retains it. Japan is apparently the only producing country of any importance in which the 12-hour day in continuous processes is still the rule. The change to three shifts has been made for social rather than economic reasons under pressure of labor and public opinion and the reduction of hours in other industries.

The 7-day week in blast furnace and some continuous steelworks operations was still common in 1932 in all the leading producing countries except the Soviet Union. In the maintenance and other non-continuous processes the 57-hour week is the rule in Germany, and the 8-hour day and 44 or 48-hour week in England; but workers in American plants often work 10 hours a day 6 days a week and in the smaller plants they usually work from 1 to 3 hours longer when there are rush orders. The French decree regulating hours in heavy industry permits work longer than 8 hours "in case of emergency," but most maintenance work may be classed as emergency work. Overtime is supposed to be paid at extra rates in France, but only for the first 140 hours of such excess per year. In the Soviet Union departures from the 8-hour day are officially prohibited, and the 7-hour day is the rule in many cases.

Comparisons of money wages in different countries can best be carried out by taking the

starting rate for unskilled adult male labor; it should be noted, however, that in Germany 86 percent of the heavy industry workers are paid on piecework or bonus systems, that in England piecework is also common and that in general the common labor rate does not have in Europe the preponderating importance it assumes in the United States. At the beginning of 1930 unskilled labor was receiving an average "normal" weekly wage, including family allowances and other social allowances, of \$7.77 in France, \$7.40 in Belgium, \$7.68 in Luxemburg and \$11.28 in Germany (this figure includes some pieceworkers). Unskilled British workers were earning about \$10.00 a week when steadily employed. Common labor in the Birmingham, Alabama, plants of the United States Steel Corporation were paid \$18.60 per week for maintenance work, and in the Pittsburgh area \$26.40. Unskilled male industrial labor in India earned in 1930 from 10 to 15 rupees (\$3.65 to \$5.48) per month, but the rate at the Jamshedpur steelworks has always been above the prevailing rate in other industries. Men's wages in Japan before 1929 ranged from \$.50 per day upward, supplemented usually by bonuses and allowances in kind. In the Soviet Union after the 40 percent increase of October 1, 1931, the day rate for the lowest grade of unskilled labor was 3½ rubles a day, which at the official quotation of foreign exchange is equivalent to \$1.80; in addition more than 20 percent is added to wages by social benefits, or "socialized wages" as the Russians call them.

The trend of real wages, defined as the power of full time money wages to buy goods and services, has been downward since 1929 in all countries except the Soviet Union. In the period from 1923 to 1929 real wages were highest in the United States, followed by England, Germany, France and Belgium. But the prevalence of unemployment in the first three countries raises doubts as to the value of estimates based on full time wages, and the apparent differential in favor of the American iron and steel workers is materially lessened in fact by the failure of the United States to provide unemployment insurance.

The differential between the lowest and highest wage rates paid in the industry appears to be greatest in the United States, where some wage earners (rollers) earned in 1929 as much as \$450 a month. It is also great in India and South Africa, where the unskilled workers are natives while the skilled workers are imported mainly

from England and are paid higher wages than they would earn at home. The differential is greater in England than on the continent of Europe. In the Soviet Union the differential was recently increased. Since October 1, 1931, workers are divided into eight earnings groups, and the ratio of earnings in the highest to those in the lowest groups is 3.7 to 1 instead of 2.8 to 1 as formerly.

Figures are lacking for a satisfactory comparison of the accident risk in the iron and steel industry of the several countries. Examination of such material as is available leads to the conclusion that accident rates have been reduced in all countries, partly through planned safety work undertaken under the stimulus of workmen's compensation laws and partly through revision of the industry's technique, but that the reduction has not been as rapid in Europe as in the large plants of the United States. Since the accident risk in the United States and Germany seems now to be roughly the same, one may infer that the American risk before the beginning of the safety campaign in 1907 was inordinately high. It is noteworthy that the early American compensation laws were modeled largely on the European, whereas the technique of safety campaigns as developed in the United States, largely on the initiative of the iron and steel industry, is now serving as a model for both public and private bodies in Europe. The advance of mechanical improvement has caused a diminution of the excessively hot work, which has made iron and steel workers especially subject to respiratory ailments, and has diminished the danger from such special occupational diseases as "hot mill cramps."

Major shifts in the relative importance of different producing areas since the war coupled with rapid technical advance in the midst of the general economic crisis have produced in Germany and England a chronically unemployed group of iron and steel workers. This group included in Great Britain about 25 percent of the wage earners in the industry during the five years beginning with 1925. But while the British blast furnace industry has been declining, and the industry in general has failed to produce more steel in any post-war year than in 1917, certain branches, such as tube manufacture, have expanded employment. In France, Belgium and Luxemburg, however, the expansion of the iron and steel industry (partly responsible for the German and British decline) necessitated recruiting labor from abroad. The depression

which began in 1929 caused unemployment in all countries except Soviet Russia, where production and employment continued to increase.

In contradistinction to the United States, where it is almost wholly absent, collective bargaining prevails to a certain extent in the European iron and steel industry. Although the industry participates in the various national plans for labor-capital cooperation, particularly in Germany, the employers usually resist unionism, which is not as highly developed as in most other industries. In the resistance to unionism the same methods are employed as in the United States—spy systems, terrorization of workers and organizers, pressure through company housing, and similar measures.

Trade unions have flourished in the British heavy industry ever since its inception. A number of these unions amalgamated in 1916 in the British Iron and Steel Trades Confederation, organized largely on an industrial union basis. Twelve years later this union claimed 53,328 members, most of them in the affiliated union known as the British Iron, Steel and Kindred Trades Association, covering skilled and semi-skilled workers in the steelworks, rolling mills and tin plate works of the whole country and the blast furnace industry of Scotland. The trend toward industrial unionism is, however, not complete; there exists an independent organization, the National Union of Blastfurnacemen, Ore Miners, Coke Workers and Kindred Trades with 15,000 members in 1928, and in addition some thousands of laborers from the heavy industry are affiliated with the National Union of General and Municipal Workers and other unions of unskilled workers. Since the war union membership has not held its own and the depression which began in 1929 precipitated a marked decline. Working conditions are regulated by collective agreements and by joint wage boards set up by government intervention. Most of the agreements contain provisions for some form of wage sliding scale regulated by the selling price of the product. This plan was formerly used quite generally in the coal and iron industries of Great Britain and the United States but has passed out of favor in the coal industry, although it persists in the unionized section of the American iron and steel industry. Since 1865, when unionism was first firmly established in the British industry, there has never been a strike (other than local stoppages) except for the walkout of the iron and steel workers during the general strike of 1926.

In England the unions of iron and steel workers are distinct from the unions of machinists and other workers in the engineering trades. On the continent, however, the organized iron and steel workers usually belong to larger unions of metal workers, which include machinists and other workers in the engineering trades. The problem of organizing the iron and steel workers in Germany has been largely the problem of penetrating the mammoth plants of Rhineland-Westphalia, which operated on a non-union basis until the outbreak of the war. The German Metal Workers' Federation claimed jurisdiction over the iron and steel industry and carried out repeated propaganda and organization campaigns in the Ruhr and Saar valleys without much success. The growth of organization during the war was rapid; in November, 1918, the first general collective agreement was signed with the organized employers in the iron and steel industry. The works councils for a time threatened the supremacy of the unions, but were finally subordinated to the unions. Many steel workers in the Ruhr participated in the miniature insurrection of 1920, which followed the Kapp *Putsch* and had for its object the overthrow of the capitalist government. The unions and employers have had frequent recourse to the machinery of arbitration set up under the new labor code. In 1928 the employers defied an arbitral decision and a lockout of about a month ensued, resulting in a compromise. The German Metal Workers' Federation in the Ruhr had about 50,000 members in 1928; an equal number of iron and steel workers are organized in the Christian Metal Workers' Federation, which rejects the socialism of the "free" unions.

The French metal workers' federation has always been industrial in form, but the unions are still largely localistic in spirit and their benefit system is relatively undeveloped. From 1905 to 1907, only a few years after the rapid development of the Briey basin had begun, the union conducted a series of bitterly fought strikes in the Longwy district of French Lorraine but was defeated. During the war the fact that the bulk of the French plants were behind the German lines and were not running prevented the growth of unionism. After the war the plants were rebuilt and greatly extended but on a non-union basis. For a number of years after the union split of 1921 neither the half which remained in the *Confédération Générale du Travail* nor the half which went over to the *Con-*

fédération Générale du Travail Unitaire (affiliated with the Red International of Labor Unions) made much progress in the Lorraine iron and steel industry, although both applied themselves to the task. As in the United States the problem of labor organization has been complicated since the World War by the fact that more than half of the iron and steel workers are immigrants, a large number of them from Poland and Italy.

About 60 percent of the workers in Belgian industry were organized in 1930, the majority in the *Centrale des Métallurgistes de Belgique*. The *Centrale*, which has a very well rounded system of benefits, was able to carry on a strike (precipitated by a lockout) of about 15,000 in the iron and steel industry of the Charleroi district for more than eight months ending in February, 1926. Since the war collective bargaining has been carried on through a national mixed commission, consisting of a president, nominated by the state, and representatives of the employers and workers, including among the latter all the unions in the industry; but the recommendations of the commission are not binding. A somewhat similar system of bargaining prevails in Luxemburg, where unionism was first established on a firm footing during the World War. It has been estimated recently that 38 percent of the heavy industry workers in Luxemburg are members of the labor union, which comprises both miners and iron and steel workers.

The history of unionism in the various countries suggests that a most important factor influencing the success of labor organization is the degree of concentration of control in industry. When one employer or a close federation of employers dominates the field, the task of the unions is very difficult. Thus the Carnegie interests in the United States were able to drive the unions out of their plants within a few years after they had emerged as the dominant steel makers of the country. All the French employers accepted the leadership of Robert Pinot in the strike of 1905-06 and have since formed very closely knit trade and employers' associations which have successfully resisted unionism. It is significant that the German employers did not lock out the workers in the post-war period until after the formation of the United Steel Works, a dominant firm with a productive capacity of 40 percent of the country's total. In England, where unionism is most strongly established, a single firm has never

dominated the industry. In India, however, the Tata Iron and Steel Company, one of the largest concerns in the country, has seen the establishment of unions among its imported skilled workers, as well as among the native workers, who put their organization to the test of a strike in 1928 after having maintained it for some years previously.

Unionization has been hampered in countries where development has been most rapid and great numbers of workers have been drawn suddenly into the industry from a rural or semi-rural background. In cases where these newcomers speak a different language, as in the United States before the war and in France, Belgium and Luxemburg after the war the problem of unionization is further complicated. Isolation from other industries has seemed to work against unions in the Saar, Luxemburg and Lorraine and in the American industry with its company towns. On the other hand the steel workers of Jamshedpur, India, have achieved organizational results despite the fact that they were for the most part recruited from an agricultural population scattered through all parts of a large and polyglot country.

In all countries, even where industrial unionism prevails, labor organization is based on the skilled workers. The unskilled have usually followed the lead of the skilled and have been unable to establish organizations of their own except where the skilled workers were already organized or organizing.

The success of unionism in the iron and steel industry of Great Britain, as compared with that of the United States, is to be explained largely on the basis of the different degree of technical development in the two countries and indirectly by the different geographical conditions that led to mass production in the one country and to relatively small scale competitive production in the other. The industrial unions of the continent have demonstrated their capacity to penetrate heavy industry, but it is not yet clear that the penetration is permanent; nevertheless, the comparative absence of craft separatism in Europe makes the problem of organization more easily solvable than in the United States. The experience of Europe has shown also the great usefulness of labor political parties in stimulating and maintaining trade union organization in the large scale trustified industries.

IRREDENTISM. The term irredentism is derived from the Italian *irredenta* (unredeemed). The concept originated in the nineteenth century in connection with the Italian movement which after the unification of Italy aimed at the annexation of Italian speaking regions still under Austrian or Swiss rule, such as Trent, Dalmatia, Istria, Trieste and Fiume. The concept, however, has become detached from its concrete and specific connotation and has come to denote any movement which aims to unite politically with its co-national mother state a region under foreign rule. Since national and political frontiers seldom coincide, irredentism belongs to those movements which since the nineteenth century have been especially directed against the political status quo.

At the basis of irredentism lies that principle of nationality which was developed by Mazzini and Mancini and which was a popular slogan of European politics at the time of Napoleon III; namely, the principle that national and political frontiers should coincide. In the field of foreign affairs this principle gives rise to irredentism; applied to domestic politics it sanctions the assimilation by the dominant majority of the subject minorities differing from it in language and race. Irredentism also finds justification in the principle of democracy, for it takes its starting point from the principle of self-determination of peoples and from the conviction that the sovereignty of a state over a given territory is legitimized not by dominion or international treaties but by the homogeneity of the population and by the consensus of opinion resulting from this homogeneity. Since democratic doctrine regards the state as an institution of national self-organization, ethnic homogeneity and national completeness of the population are decisive guarantees for the stability of the state. All other motives, such as regard for the sacredness of treaties and of the oath of allegiance, are sacrificed for the sake of this supreme principle. Accordingly Masaryk proclaimed the primacy of national loyalty over state loyalty, thus virtually sanctioning high treason.

The development of these principles provided a moral and psychological basis for revolutionary nationalism, which with the aid of modern methods of organization and propaganda supplied the border populations with a technique of rebellion against their political sovereigns. This propaganda is, on the one hand, carried on by organizations consisting of the dissatisfied elements of the irredentist population who appeal

to the mother state for help; and, on the other hand, by the press, associations and parties in the neighboring state, which working secretly and generally also as indirect organs of the state are interested in the fate of the co-national region and in preparing for its future annexation. This often gives rise to serious international friction, as in the case of the Austro-Serbian relations during the period before the World War and in the German-Italian friction over the German population in the Tyrol. In the decades that preceded the war the extremist elements of the irredentist regions in Italy developed a technique which enabled them to keep in constant touch with the influential spokesmen of the masses in the mother state. The Italian government, however, in view of its alliance with Austria-Hungary kept aloof from these tendencies of national solidarity and sometimes even disavowed them; but after the interventionists carried the day in the World War it formally gave up its dualistic policy in favor of an outspoken policy of conquest, which it carried even beyond the irredentist regions in the proper sense of the term, extending its claims to purely German and purely Slav provinces.

Within the territories inhabited by the irredentist groups irredentism does not find active support among those elements whose interests may be adversely affected by a change in the status quo or by any revolutionary and military convulsions. This is particularly true of those persons who are prevented by professional and business interests or by social position from embarking upon a policy of open national partisanship and of opposition to the existing state power and its organs. Irredentism is championed most passionately by the youth, by academic circles, by certain liberal professions and by the press in so far as any articulate expressions are permitted by the state. The majority of the population is usually ready to compromise and to accept the traditional rule and the customary boundaries, restricting its activities to seeking more favorable national-cultural and economic conditions. Very often its attitude is opportunistic and it is the first to join the irredentist movement as soon as it gives promise of achieving success. The differences, however, between the groups and classes which keep aloof from irredentism and those which actively support it tend to become more relative and less rigid as the state and the nationalism of the dominant majority begin to interfere with the life of the individual.

The history of Europe even before the World

War shows that wars are never a remedy for irredentism. Some border territories, like Macedonia, contain populations whose ethnic and national make up is most difficult to determine; and in very large territories of mixed population it is impossible to draw a sharp line of territorial demarcation between the various ethnic communities. New national frontiers set up by peace treaties almost invariably leave some elements dissatisfied and merely serve to call forth new irredentist movements. The difficulties of solving irredentist problems in this way are clearly illustrated in the treaties of Versailles, Saint-Germain and the Trianon, which represent the most far reaching attempt ever made to reorganize large territories on the principle of nationality. Although official sanction was given to the principle of national self-determination and an important aspect of irredentism was thus recognized as a basis for the new order, the Paris Peace Conference was unable to carry out this principle in a practical way because of the selfishness of the victorious nations as well as the obstacles offered by geo-political and economic factors. As a result foreign rule was extended not only over outlying scattered settlements but also over territories compactly inhabited by subject peoples; and thus germs for new irredentist movements were planted. German border regions came under the dominion of France, Belgium, Denmark, Lithuania, Poland, Hungary, Czechoslovakia, Rumania, Yugoslavia and Italy; strong irredentist tendencies have developed among the Magyars in the territories which Hungary had to cede to Czechoslovakia, Rumania and Yugoslavia; there is a Bulgarian irredentism which is directed against Rumania in Dobruja and against Yugoslavia in Macedonia; the Ukrainian, White Russian and Flemish questions are still unsolved or unsatisfactorily settled. In all about 40,000,000 people belonging to ethnic minorities remain in a state of national discontent.

As counter-remedies for irredentist difficulties three methods have been suggested: the rectification of frontiers, assimilation and accord of interests. A state that rules over a foreign territory against the will of its inhabitants may voluntarily renounce for higher reasons of state or under military or revolutionary compulsion the exercise of its sovereignty and allow the territory either to become independent or to join the co-national state. Generally a union of this sort, even though it might redound to the benefit of the renouncing state, is prevented by reasons of

prestige or by the possibility of repercussion upon domestic and international politics.

Instead of regarding the seat of sovereignty as variable and adapting state affiliations to the ethnic structure and the racial will, the method of assimilation is often attempted. The dominant national group tries to destroy the roots of irredentism through the denationalization of minorities by assimilating the heterogeneous groups with the dominant national majority. The degree of compulsion which is applied is determined by various factors. It depends upon whether and how far the racial minorities are prompted by extra-ethnic interests to remain within the original state union and how far the assimilatory tendencies of the state have been furthered by the existence of self-assimilatory tendencies in the subject racial groups or in certain social elements. It is also true that it is not always possible to change the political affiliations of a group without calling forth religious, economic, social and cultural transformations. If these changes signify a new form of suppression, the process of assimilation is rendered difficult. Other factors, such as economic enrichment, a rise in the educational level and social advance, indirectly further assimilation.

If the attempt to change both the dominant sovereignty and the ethnic character of the racial groups is abandoned, then a compromise must be found outside the alternative between irredentism and assimilation—between revolt against the state on the one hand and extermination of nationality on the other. Tolerance on the part of the state and loyalty on the part of the racial groups are here in a relationship of natural reciprocity in so far as tolerance is not a sign of weakness and loyalty is not an expression of national indifference. The aim must be to find political and national forms which would enable the members of the subject racial minorities to participate in the general life of the state without affecting their national ideals and to take an interest in the life of their groups without interfering with their patriotism toward the state. A harmony must be established between loyalty to the state and adherence to the life of the national group, although the two do not coincide. If the attempt is made to satisfy the members of the minorities upon a more individualistic basis, then the state must above all give them full rights both *de facto* and *de jure* in all walks of life. Moreover the state must guarantee the individual a sufficiently extensive private sphere either as a matter of general policy or as a special

privilege for the subject minorities. One of the chief causes of irredentism lies precisely in the attempt on the part of the state to interfere with spheres which formerly were outside state jurisdiction. The corporative forms of satisfying the various national groups involve the granting of national autonomy either on a personal or on a territorial basis. This enables the minorities to develop special co-national spheres, either objective or locally delimited, which do not interfere with the sovereignty of the dominant state. In the former case the danger of irredentism for a given state is mitigated by the mutual isolation of the members of the minorities. In the latter case the autonomistic method with general decentralization, regional self-government and cultural autonomy offers through the segregation of minorities as wholes an excellent means of avoiding conflicts between the will of the groups and the authority of the state or of confining possible frictions to isolated cases.

During the post-war period no steps have been taken to redraw obviously unpractical boundary lines to satisfy ethnic discords. Even in the case of Eupen-Malmédy, where both Belgium and Germany as well as the affected population itself have been friendly to a revision, nothing has been done because of the objections made by France. Only in exceptional cases have states displayed a readiness to abandon assimilatory policies. The situation of the minorities has been made especially precarious by such important contemporary tendencies as plebiscitary democracy, state socialism in the economic and cultural fields, fascism and national socialism, collectivism and mass terror. On the other hand, the task of assimilation is rendered equally difficult by the general state of education, by the general increase of national consciousness and by the wide diffusion of the theories of political nationalism. The failure of the revision of frontiers combined with an intensified assimilatory pressure consequently tends to foster the discontent of the minorities and in this way to further irredentism.

Two types of method have been resorted to in the post-war period in order to counteract national oppression and irredentism. One method is the international legal protection of minorities provided for by the Treaty of Versailles, whereby provisions were made for possible appeal to the Permanent Court of International Justice at The Hague. The starting point of this method is thoroughly individualistic. Its aim is essentially to guarantee through international supervision

equality in civic and political rights to the individual members of the minorities even in opposition to the parliament and the administration. The tendency is here to transform political conflicts into juridical procedures upon the basis of international law and in this way to check the irredentism of the racial groups. The protective procedure is of a schematic and general nature; it clings, however, to positive treaties and declarations. But on the one hand it does not go deeply enough into the principles upon which the relation between state and nation is based, and on the other hand it fails to do justice to the concrete relations obtaining between individual states and national groups. This method has proved to be entirely ineffective for righting wrongs committed by states. Its chief significance is prophylactic; its function probably lies in the prevention of further acts of violence, whose extent naturally cannot be estimated with exactness. As shown by the examples of Italy and France it has scarcely any effect upon the domestic policies of those states which although they are members of the League of Nations and partners in protective treaties are not formally obliged to protect minorities.

More promising and effective are the attempts made by individual states, such as Prussia, Estonia, Czechoslovakia and others, to regulate the question of minorities legally and within the sphere of domestic politics. In these instances the state has exhibited a more tolerant and just attitude toward its minorities, and the state legislature and administration have recognized and stimulated the latter's autonomous institutions. Whether and to what extent these attempts will check irredentist developments cannot yet be foreseen. The future of irredentism will depend upon how far the consciousness of the age will be affected by the principle of nationality and consequently by the ideal of a national state in which national and political frontiers coincide. As long as the belief is current that the function of the state is to enable a particular ethnic individuality to assert itself and to exercise power, it inevitably follows that the state territory must be completed in accordance with ethnic frontiers and that all ethnically homogeneous territories must be united in one political whole.

IRRIGATION is the process of artificially supplying water for agriculture in regions where rainfall is deficient or lacking. From remote antiquity the peoples of the tropics have cultivated food and fiber crops by its aid, and many of their institutions have arisen in part from the cooperative nature of this undertaking. In the modern world irrigation has often been motivated by purposes other than the conservation of the food supply or the cultivation of industrial plants for local needs. In the United States and throughout large areas of the British dominions irrigation projects have been inaugurated upon territory of small or no population, with the aim of establishing in these regions communities of agricultural farmers. A nucleus of such farming families eventually becomes a township; other industries are attracted and the result is a commercial agricultural economy in which crops are grown for export, and transport and banking facilities soon appear. Irrigation thus aids in the settlement of a formerly barren region, frequently by emigrants from congested areas.

The modern irrigation works installed by the British in Egypt and by the French in northern Africa have as one of their objects the desire to assure the necessary food supply for the native peoples; of equal importance, however, is the wish to provide water for capitalistic enterprise. In Egypt the latter is concerned with cotton; in northern Africa with fruit, especially dates. In sparsely populated Mesopotamia native irrigation methods suffice for local needs, but the soil and temperature are preeminently suitable for cotton, a raw material in which the British Empire is deficient. At present in Mesopotamia several small irrigation projects are already in operation, although more ambitious schemes have been under consideration and in the future may become possible.

A few European countries practise some seasonal irrigation. A summer irrigation in the Po plain provides for rice and for the mulberry, which is cultivated for silkworms. Irrigation in the Roman Campagna now furnishes both good

pasture and forage for fattening livestock in winter and a summer harvest of fruit and is leading to the replacement of a temporary by a permanent population. The terrace and *huerta* gardening of Spain provides for oranges (of which there is a considerable export), other fruits and esparto grass as well as cereals for home consumption. Although irrigation is of long standing in Asiatic, it is in its infancy in European, Russia. The reorganization of agriculture under the Five-Year Plan embodies an elaborate program of irrigation for the wheat, forage and other crops in the Ukraine and the Caucasus. The dense populations of the Far East could not raise sufficient food without irrigation; in India it has largely banished famine; in China the system of multiple cropping and intertillage raises enormous harvests by utilizing field ditches for rice cultivation in water which through seepage irrigates the other crops grown upon the intervening banks.

The recovery of underground water by sinking wells early supported a little agriculture among tribes that were preponderantly pastoral. Surer results were obtained where rivers crossing arid territory could be dammed by a crude barrier of earth or stones, forming reservoirs from which simple channels might be led out to the fields. The corn and food crops of ancient Mexico were thus irrigated from mountain streams, and the early Mormon irrigation was of the same type. This method is still in use upon the Deccan of India and elsewhere in the East.

Taking advantage of the fact that inundation of riverine lands might be considerable when floods were heavy, the pharaohs of ancient Egypt elaborated the "basin," or "flood," system of irrigation. A longitudinal dike parallel to the bank of the river secured the left side of the valley from the exceptionally high floods that swept down it every eight or ten years. Shorter, transverse dikes stretched from the long dike to the Libyan hills, thus dividing the country into compartments or basins with an average area of 7000 acres. Where the valley was narrow these basins were not more than 2000 acres in size; where it was wide they averaged 20,000 acres. Groups of seven or eight basins were served by a feeding canal fitted with regulators, which led the turbid flood waters into one basin after another beginning at the lowest, the furthest from the intake on the Nile. The waters stood on the land for about forty or forty-five days and then returned to the subsiding Nile through breaches

in the embankment walls and through escape channels in the tail basins. Each flood deposited fertile alluvium, and the ground was ready for sowing in November. This process of reclamation was eventually repeated on the right side of the valley; and since the double longitudinal dike might cause inundations throughout Lower Egypt in years of exceptional flood, natural channels enlarged for the purpose diverted these waters to the Faiyum depression to form the so-called Lake Moeris. Similar channels took the excess back to the Nile when the flood season was over; but ultimately the river widened and built up its own trough, in which it remained. Thus Lake Moeris, now no longer required as a safety valve, has been reclaimed for agriculture.

The contemporaneous irrigation of Babylonia involved two rivers, each carrying about five times as much silt as the Nile. The floods occurred too late for winter and rather early for summer cultivation, so that Babylonia evolved what may be called the perennial system of irrigation, which made agriculture possible at practically all seasons. The salt deposit resulting from a temporary overflow of the Euphrates as well as the liability of the flooded Tigris to excessive inundation necessitated careful drainage. Powerful escapes took the Euphrates floods into two depressions northwest of Babylon, thus providing reservoirs for feeding the river when low. The Tigris had two large canals, one on each bank and more or less parallel to it. The more important left bank canal possessed three heads, so that when one was closed for desilting, the system was still in working order. The canals filled naturally in flood time; but when the river was low, sections were flooded with reserves stored behind huge storage dams of rubble or brickwork. Gigantic regulators for filling and emptying the canals and thousands of miles of subsidiary channels were part of this system, which resulted in flourishing cities and a phenomenal agricultural return.

A species of basin irrigation (more accurately called overflow irrigation) was a feature of the Ganges and Damodar deltas more than 3000 years ago. Shallow channels were constructed at right angles to the river in order to draw off the upper layers of the flood waters, where the silt was finest. Breaches in the canal walls, closed after use, supplied the cultivable tracts. Irrigation took place during the monsoon rains for the double purpose of manuring soil exhausted by rice crops and of combating malaria, because silted water destroys the mosquito. When the

Chola kings of Bengal conquered southern India they imposed this system on the country, where it is still in use although it has vanished from its original home.

The ancient form of irrigation in Ceylon was the tank, constructed for the irrigation of rice. The larger tanks occupied natural depressions, whose walls were heightened by earthworks. They were fed by canals drawing from reservoirs created in a river by means of barrages of masonry or brickwork, the more permanent of which were fitted with valves and sluice gates. The largest tanks covered from 4000 to 6000 acres, although the general magnitude was much less; the heavy constructional expenses were met by the royal exchequer. Similar tanks were built in Madras; two of these, one irrigating 3000 and the other 4000 acres, are still in working order although over eleven hundred years old. In peninsular India and Ceylon small tanks, constructed by the cooperative labor of the village community and generally filled by the monsoon run-off, have been in use since remote times.

The earliest monster irrigation project in China was the ingenious dike by which the Min River floods spread out laterally in numerous channels, carrying irrigation to the Red Basin of Szechwan. The scheme was planned and installed by two successive hereditary governors of Cheng-tufu between 250 and 200 B.C. Extensively repaired in the thirteenth century, this great work still furnishes the major part of the irrigation in the Chengtu plain.

Stupendous engineering feats necessitated by adverse topography were a feature of the Inca irrigation. Massive masonry dams, cisterns carved in solid rock, canals and subterranean aqueducts lined with freestone slabs were the characteristics of these irrigation constructions effected by a people living in its stone age.

The "terrace" irrigation practised by the Moors in the Old World and the Amerinds in the New World deserves special mention. In this system water drawn from either mountain streams or reservoirs filled by rain or water lifts flows over successive terraces constructed on a hillside. Primitive harrowing or a low outer wall allows a small amount of water to remain after the sheet has passed. Terrace irrigation spread in the wake of the conquering Arabs westward across Africa and into Spain in the eighth century and eastward to India and the Far East, where it still flourishes. It is also highly developed in the intermontane valleys of the Andes ranges.

Generally speaking the king or the state working through him was responsible for the larger engineering constructions, while local boards of magnates, as in Egypt, or of peasants, as in Bengal, adjusted the individual amounts of water and settled disputes between users. In Egypt the law exercised a general control with regard to the dikes, while the basins and their canals were kept in order by local *corvée*. Slaves and captives were employed for the diking, for which local quarries supplied stone. The small state expenses were met by the land tax, and the water was otherwise free. The efficacy of the Mesopotamian irrigation depended upon the power wielded by the central authority and was greatest when one king held the whole of the Tigris-Euphrates trough. The labor of desilting the canals was so arduous that it could be undertaken only by royal *corvée*, and probably much of the Babylonian aggression arose from the need to obtain captives for this purpose. Townships and landowners along the course of the river dealt with local silt and drainage difficulties.

Apart from its aid to agriculture irrigation conferred other benefits. The mutual interest of the cultivators in the available water developed a spirit of association which went far in promoting common action for the attainment of a common aim. In the ancient world the irrigation empires were the most coherent and the strongest, as they were also the most advanced in the learning and science of the times. When irrigation produced surplus crops, a medium of exchange was provided leading to oversea trade and a cultural link with other lands. Egyptian grain was of special value to countries with fewer agricultural advantages, a factor which undoubtedly contributed to its many invasions. Particularly was this true of the conquest of the country by Caesar Augustus: with a failing Italian food supply the Egyptian fields were vital to the maintenance of the Roman Empire.

In modern times irrigation on the pioneer fringe has been a cooperative venture; the necessary dams and ditches have been constructed by the water users. The earliest of these pioneer enterprises was the Mormon irrigation in Utah, where there sprang up flourishing settlements based on an agriculture fed from the diverted waters of the mountain streams. These early experiments in Utah showed that harvests could be gathered from the by no means infertile soil of the far west; irrigation companies were formed for profit, with the result that the actual cultivators became mere purchasers of water rights. But

such schemes were never really successful, because settlement was slow and the original estimates of possible revenues for shareholders could not be realized; again, western states enacted laws rendering illegal the demand for the payment of a water service charge (over and above the original purchase price of the water right). Cooperative and commercial enterprises are still to be found, but irrigation has very generally entered upon a third phase, in which reclamation on a large scale and in the more difficult regions has become the concern of public authority. Such projects in the United States are carried out under the supervision of the federal Reclamation Bureau; similar bodies function in the Union of South Africa and the separate states of Australia and provinces of Canada.

Irrigation sometimes gives rise to problems of more than local significance. One of the most frequently recurring of these is the equitable use of a river supplying a number of jurisdictions. In the United States, for example, recourse to interstate compacts has been necessary; typical are the one governing the use of the waters of the South Platte River, entered into by Nebraska and Colorado, and the Colorado River compact, to which six southwestern states are parties. A similar problem arises when rivers suitable for irrigation cross countries under different governments. The state possessing the source waters may divert needed water downstream. Difficulties sometimes spring up when a river technically navigable becomes too shallow through excessive use of its waters for irrigation.

By 1930 some 200,000,000 acres throughout the world were under irrigation. In North America the United States led with 20,471,000 acres, in Mexico there were 5,700,000 acres, in Canada 400,000 acres. In South America, Argentina was the principal user of the method with 3,000,000 acres being watered by ditches, Chile had 2,458,000 acres and Peru 1,000,000 acres. In Europe, France led with 6,000,000 acres, Italy had 3,900,000 acres, Spain 3,500,000 acres and Portugal 1,200,000 acres. In Asia and Oceania, India had 55,800,000 acres artificially watered, China had 50,000,000 acres, Java had 8,350,000 acres, Asiatic Russia had 8,000,000 acres, Japan had 6,675,000 acres, French Indo-China had 3,470,000 acres, Siam had 1,750,000 acres, Mesopotamia had 1,500,000 acres, Australia had 1,000,000 acres, the Philippine Islands had 750,000 acres, Ceylon had 350,000 acres. In Africa, Egypt led with 6,000,000 acres, while Morocco

had 1,500,000 acres, South Africa 800,000 acres and Algeria 400,000 acres.

The value of irrigation may be considered under three heads: local needs, cash crops for export and the maintenance of the livestock industry. In the first category belongs most oasis irrigation. In Iran and Soviet Turkestan such irrigation depends upon glacier fed streams; and cereals, fruit and cotton crops (some of which are exported) are the main products. In general the Saharan oases are fed from underground water, although some depend on mountain streams. In Egypt, India and the Far East as well as in Spain, Italy and other countries of Europe irrigation is employed largely to fulfil domestic requirements. Terrace agriculture largely serves local needs, although at times it provides exports to neighboring mining centers and other nearby settlements. In the second category are the cereals, temperate fruits and cotton crops of the newly developed lands of America and the British dominions as well as the date crops of the recently created oases in northern Africa. Irrigation belonging to the third category may be used to promote good alpine grazing grounds and valley pastures, where at the appropriate season the natural grassland can be abundantly cropped or cut for winter forage. Such irrigated pastures are a feature of the pastoral economy of southern Europe and are also to be met with in the Netherlands. In other cases the irrigation is supplied to meadows created by the deliberate sowing of one or more forage grasses of special excellence. The marcite fields of the Po valley and the "made meadows" of the Provençal plains and a number of mountain valleys of Europe have revolutionized the pastoral life of these countries. The large crops of irrigated alfalfa and hay grasses raised in western North America, southern Australia and South Africa are utilized in fattening stock for the meat industry or in feeding dairy cattle.

The effects of government programs for irrigation have at times been very unexpected. In the Old World the chief aim was the securing of sufficient food for the native peoples, but the magnitude of the operations have made other developments possible. In Egypt water is now provided for the growing of cotton, and the natives sell their crops to the state domains or private companies. New storage dams are being projected and the existing irrigation area is likely to be considerably increased. In the French Sahara the creation of oases is winning over some of the nomads to an agricultural life and at the

same time provides centers of order which will assist in checking the depredations of the wandering tribesmen.

The advance of irrigation does not go on unchecked, nor is it without its drawbacks. The transformation of Mesopotamia is likely to be delayed by difficulties arising from sparse population, political unrest and the nomadic tendencies of a large part of the inhabitants. In the French colonies the natives persist in clinging to their primitive modes of agriculture and succeed in disregarding, sometimes quite effectively, the advantages brought by an increase of water and new transport facilities. Deficient drainage is a great menace wherever there is irrigation on a large scale. Underground accumulation of unused irrigation water may lead to waterlogging, which destroys crops and may even cause the formation of swamps. Such underground water is likely to bring up to the surface deposits of mineral matter, which form infertile salty tracts. A delicate situation arises when modern works assuring a perennial irrigation are imposed upon a densely populated country accustomed only to seasonal irrigation. The absence of fallow causes soil exhaustion which can be remedied only by expensive manuring, a condition which has manifested itself in Egypt. Moreover the increased production of cereals and fiber crops through the opening by irrigation of marginal and submarginal lands has already proved to be by no means wholly advantageous. These additional crops have merely succeeded in increasing large world carryovers and have depressed prices to such a point that since 1930 the growing of grains and industrial plants has, except where acreage has been drastically restricted, seemed on the whole commercially unprofitable.

ISABELLA OF CASTILE. See FERDINAND V AND ISABELLA.

ISELIN, ISAAK (1728-82), Swiss historian and economist. Iselin's works are all animated by the optimistic eudaemonism of the Enlightenment and the endeavor to trace the process whereby mankind developed from barbarism to higher perfection. As a disciple of Leibniz and Wolff he emphasized the predominance of reason. He protested against Rousseau's glorification of the natural man and looked for the stage of man's perfection not in the past but in the future. He classified historical eras into periods of youth, maturity and decay and considered the phase represented by maturity as the climax of development. Unlike Herder he denied any cultural values to the non-western peoples and to the whole period of the Middle Ages. He gave particular emphasis to the cultural significance of the ancient world.

In his theory of the state Iselin opposed the contract theory and called it chimerical and a fiction. His theory was closer to that of the *consensus tacitus* which served as a transition form from the social contract theory to the organic concept of the state. The motives which led to the rise of the state were the gregarious instinct, the habit of obedience and the desire to command. In accord with his ideas of progress and perfectibility he was also a disciple of Basedow in his interest in education and philanthropy.

In his economic views Iselin was influenced by the physiocrats. Like them he distinguished between the actual and the normative ideal orders. From the standpoint of a theory of imputation he also favored the physiocratic classi-

fication of individuals as advantageous for a distinct evaluation of the economic value of the several classes. This, however, was but an abstracting process, and a certain balance of classes and occupations was necessary as a guaranty of a well functioning economic society. Iselin also favored an international economic balance of power, in the sense of an international division of labor, in order that the process of economic circulation be not impeded. Although from the purely economic standpoint "net proceeds" are attributed to the landowner alone, a part thereof in the form of taxes belongs to the state which assures the owner peaceful possession. Iselin opposed all forms of constraint and considered freedom of commerce and trade as the best regulator of prices. He also advocated the classic principle of preestablished harmony according to which the happiness of the individual is closely bound up with that of his fellow men.

ISIDORE OF SEVILLE (Isidorus Hispaniensis) (c. 560-636), mediaeval Spanish encyclopaedist. Isidore was both the last of the early Christian philosophers, the direct descendant of Boethius and Cassiodorus, and the forerunner of the scholastics, the pioneer of the great revival of learning in the thirteenth century. He is the originator of the encyclopaedia, the first to compile a *summa* of all available knowledge. The greatest of his works, the *Etymologiarum sive originum* (ed. by W. M. Lindsay, 2 vols., Oxford 1911), with its twenty books subdivided into more than three hundred chapters, is a compendium of seventh century scholarship and a library of information. Isidore drew freely from the classic Latin writers, from St. Augustine and St. Jerome and from Boethius, Gregory the Great and the Latin fathers of the Christian church. His work enjoyed a wide popularity among students throughout the early Middle

Ages and was translated into the vernacular not only of his native land but of other European countries. In the progress of learning the influence of Isidore is discerned in shaping the form of knowledge and directing the mind to universals rather than to special subjects. He anticipated the work of Peter Lombard, Albertus Magnus and Thomas Aquinas. All that could be saved of Greek and Latin culture in the break up of the Roman Empire was carefully guarded by Isidore and he is credited, perhaps justly, with introducing the writings of Aristotle to the west.

In Spain as archbishop of Seville, Isidore was conspicuously an instrument of reconciliation in fusing the ancient civilization of Rome with the Visigothic elements. No less was he an active force in the education of the clergy. The Fourth National Council of Toledo (633-34), held during Isidore's archepiscopate, ordered the establishment of seminaries for clerical students—a reform in the standard of learning that had to wait for the Council of Trent before it was generally enjoined. Isidore's educational policy also required that Hebrew and Greek must be taught and fresh incentive given to Biblical studies.

ISLAM is the name of the youngest of the great world religions. The word itself means submission—that is, submission of believers to Allah and his prophet—and may denote the primitive preaching of Mohammed (*q.v.*) as well as the sensibly different later orthodox system or the folk religion of the modern Moslems. Islam is, however, more than a religion; it represents also a political and juristic theory which has been at least partially realized in one of the greatest oriental world empires and in numerous separate states extending down to the Moslem states of the present day. Finally, Islam signifies a cultural whole, encompassing religion and state, since the concept of Islamic state and the tenets of Islamic civilization derive their authority solely from their foundation in religion. The ideal of Islam is the rule of religion over all of life; as a religion it is at the same time the

Weltanschauung and way of life of its believers. In its foundations and in numerous features Islamic culture is closely related to the Christian culture of the Middle Ages and is derived from the same roots.

Islam arose in Arabia, where in Mohammed's time paganism had ceased to exercise any spiritual sway and where pagan rites were practised as a part of tradition or, as in the annual pilgrimage to Mecca and the observance of the holy months, chiefly because of their economic value. Even before the days of Mohammed some Arabs, the so-called Hanifs, had turned from paganism but without embracing either Judaism or Christianity. The evolution of monotheistic tendencies was aided by the influence of these two religions, both of which had numerous adherents in Arabia. Jews, chiefly converts of Arab descent, dwelt in compact groups in the oases of western Arabia. Christianity had spread, although as a rule superficially, toward the north and east from the Christian-Arab buffer states set up by the Roman and Persian empires. In the period immediately preceding Mohammed, Allah had begun to be recognized among the mass of individual gods as a supreme deity of universal character, so that Mohammed's preaching aroused contradiction not because of his cult of Allah but because of his insistence on the exclusive worship of Allah. Thus Mohammed could restrict himself to Islamizing the cult of Mecca, while retaining its essential ancient forms; that is, the cult of the Caaba and the adjacent shrines and the so-called *hajj* of Arafat, which together form the principal elements of the Islamic pilgrimage. From its very beginnings in the seventh century Islam was not a desert cult but a typically civilized or urban religion, which was only externally influenced by Arab paganism. It was, however, profoundly affected by Arab society, especially by its dominant tribal spirit strongly bound in tradition.

The main religious tenets of Islam were derived from Judaism and heretical gnostic Christianity, although it cannot be assumed that Mohammed possessed any exact knowledge of either religion. He felt himself called upon, however, to proclaim to the Arabs the divine revelation which the Jewish and Christian peoples had already received through Moses and Jesus; and the Koran is the Arabic edition of the earlier Scriptures, with which it agrees in content. When the Jews refused to acknowledge him as a prophet, Mohammed became convinced that their Scriptures had been falsified. He accord-

ingly invoked Abraham against them and proposed to restore and propagate Hanifism, Abraham's uncorrupted religion; the institutions retained from Arab paganism were also ascribed to the religion of Abraham. These steps marked a definite break with Judaism and Christianity. Mohammed ceased to regard Islam as a form of revelation ranking equally with them and proclaimed it the only true religion.

The starting point of Mohammed's teachings is the idea of the day of judgment, which he at first considered imminent and which was to put an end to the materialistic activities of the inhabitants of Mecca if they did not do penance; the judge is Allah himself. There results from this eschatology a belief in monotheism. Man is a slave in his relationship to Allah, who is omnipotent but kind. In the Koran predestination and free will are emphasized alternately, depending upon the situation; this gave rise later to the problem of the freedom of the will. Within the prophetology of the Koran, which is related to the gnostic concept of the cyclical renewal of unitary original revelation, there appears a special form of Christology in content resembling the apocryphal Gospels, which is basically Docetic and which denies the divinity of Jesus. For Mohammed the conviction of his prophetic mission was at first simply the presupposition of his teachings, but later it developed into a fundamental dogma. He considered the essential elements of a revealed religion the possession of a holy scripture and the use of that scripture in divine services. From this doctrine is derived the significance of the Koran, whose authenticity and completeness are unquestioned. The Koran is Allah's uncreated word in the sense that in its actual form, in its Arabic language, it is supposed to be the identical reproduction of the celestial original. The use of the Arabic tongue in the Koran is important in that it determines the essentially Arabic coloring of Islam. As a source of religious doctrine it is supplemented by the way of life (Sunna) of the prophet, as laid down in the tradition (Hadith). The role of the Sunna is best illustrated by the fact that in Islam Sunnite is synonymous with orthodox. Mohammed's religious authority, even beyond the statements of the Koran, could not be questioned, and soon after his death people began to cite him as a model. In the meanwhile religious institutions and doctrines continued to develop under Jewish, Christian and Persian influences. If Islam was to maintain its position as an independent

religion it had no choice but to pretend that these elements were traditions emanating from the prophet himself. Finally, there was no better way of establishing disputed points of view than to ascribe them to the words of Mohammed. Thus everything absorbed by Islam during the course of its first few centuries had to be stamped by a gigantic fiction as the Sunna of the prophet and put into the form of the Hadith, as a result of which the true kernel of tradition was almost entirely concealed. In the ninth century canonical collections were made from the huge mass of orally transmitted traditions.

Originally Islamic dogmatics not only served as apologetics toward non-Moslems but were also directed against the literalness of the old fashioned orthodoxy. Questions of dogma were raised also in connection with political issues. The first theological school, which dates from the eighth century, was that of the so-called Motazilites, whose endeavors centered about a number of detailed problems. In part these were of a purely dogmatic nature—questions concerning the unity of God, the uncreated nature of the word of God and the freedom of the will—and their treatment revealed the influence of dogmatic discussions among Christians. Other problems, such as the attitude toward authority and the consequences of grave sins, were of political importance. The problem of the freedom of the will and semipolitical questions had been treated in a similar fashion even earlier by the schools of the so-called Quadarites and Murjiites, but Islamic theology did not attain full development until the tenth century, when the intellectual labors of the Motazilites were reconciled with traditional orthodoxy through a refined dialectical technique of Greek origin. By the eleventh century Islam had attained in all its essentials the definitive form which was to determine its future course. The orthodox system had been developed and, although evolution did not cease entirely, an increasing degree of rigidity and stagnation became evident in intellectual life. The development attained at that time was generally regarded as both elemental and final; all innovations were looked upon as abhorrent.

The legalism and rigidity which characterized orthodox Islamic doctrine led at an early period to a reaction in the direction of mysticism. The classical development of mysticism (Sufism), which took place principally during the ninth century, represents the infiltration into Islam of the Christian-gnostic type of piety with its

characteristic ascetic features, retirement from the world and the love of God, which lead to a renunciation of worldly goods and activities. Three principal trends were evident in its later evolution: first, there is a striving for mystical union through the renunciation of personality and through ecstasy; secondly, there is the desire for individual salvation, which leads to an esotericism of the holy and to an easy disregard of the law intended for the masses of the people; and, finally, there is the association with the philosophy of late antiquity, as a result of which mysticism becomes gnostic. The reconciliation of moderate mysticism with orthodox dogma and law was effected by al-Ghazzālī (1058-1111), whose influence has persisted down to the present day. Non-orthodox mysticism tended toward excesses and exaggeration. In the twelfth century arose the religious orders which popularized mysticism. They were the heirs of the worship associations of late antiquity and together with the veneration of saints give popular Islam its local color.

At the opposite pole from mysticism there existed a traditional school that was dissatisfied even with the orthodox doctrine; this school proposed in the name of a rigid concept of the Sunna to restore Islam to its early purity—that is, to the teachings of the prophet and the practises of his associates—not of course with any historical accuracy but as they appeared in the embellishments of tradition. A vigorous advocate of this school, ibn-Taymiya (1263-1328), thundered against the formulae of dogma and the teachings of mysticism as well as against the worship of the prophet and the saints, which he denounced as a departure from monotheism. His doctrine was taken up by the religious-political movement of the Wahhabites.

In addition to these general religious tendencies, which in the course of time have transformed Islam, there arose numerous sects which from an early period threatened its spiritual and political unity. They were impelled, as was natural enough in a theocracy, by religious-political motives. The first sect was that of the Kharijites (secessionists), which developed soon after the death of Mohammed and which demanded the free election of the most worthy man as caliph regardless of whether or not he belonged to the tribe of the Quraysh, Mohammed's tribe, and which also insisted on the rights of the community continually to check the leader and to depose him if he violated his obligations. Like all Islamic sects it broke up into

several separate branches, whose rebellions continued to give the state serious concern. For a time the Kharijites dominated north Africa and established communities of their own; today their scant survivors, the Ibadites, live in north Africa, Oman and Zanzibar.

At the opposite pole from the democratic Kharijites there was the legitimist Shī'a, the "party" of 'Ali, the son-in-law of the prophet, which included all degrees of 'Ali veneration, ranging from an almost orthodox esteem to an un-Islamic idolatry. At an early date the opinion began to prevail among the adherents of 'Ali that 'Ali, as the son-in-law of the prophet, was alone entitled to the caliphate; this was to become the fundamental Shiite dogma and to separate the Shiites from Sunnite Islam. The misfortunes of 'Ali and his descendants, which were largely of their own making, merely increased the veneration for the "family of the prophet." Among the countless Shiite groups the very moderate Zaidites, who are just at the boundary of orthodoxy, represent the old Arabic Shī'a. They acknowledge the caliphate of the first three caliphs and restrict subsequent caliphates to 'Ali and his descendants, but they repudiate the more extreme imam theory. They have persisted in southern Arabia since the ninth century. Outside Arabia the Shiites have become a rallying point for all revolutionary and heterodox tendencies among the Islamic peoples. Their fundamental doctrine is the imam theory. The first imam, as they prefer to call the leader of the community, was 'Ali, named by the prophet himself but deprived of his rights by the first three caliphs. The imamate is handed down to his descendants, and the problem of the line of this succession has given rise to numerous party splits. The imams are without sin and infallible and, as the bearers of a special inspiration, the authoritative interpreters of the divine will. The Sunna of the imams takes the place of the Sunna of the prophet's associates, who sinned against 'Ali.

As opposed to Sunnism, which is governed by universal agreement, Shiitism represents an authoritarian church. Persecutions limited the Shī'a chiefly to secret propaganda and gave it an air of martyrdom. The concept of the suffering of the imam and of the salvation of the faithful thus achieved assumed a dominant role. After the failure of all the Shiite rebellions there arose the conviction that the last imam had vanished in a miraculous manner and that he awaits the time when he will return as the

Mahdi, "he who is guided aright" to restore order in Islam. The split between the "Twelvers," or Imamites, who have the largest number of adherents, chiefly in Persia, Iraq and India, and the "Seveners," or Ismaelites, was the chief break in the ranks of the Shiites; they are differentiated by the number of imams whom they acknowledge. The Seveners champion the doctrine that the Mahdi, as the last of the prophets, carries on and completes the work of Mohammed; in conflict with this doctrine stands the Islamic conviction of the ultimate nature of Mohammed's mission. The Assassins and the Bohras as well as the Khojas, who still exist in India under the Agha Khān, are branches of the Seveners. Other Shiite sects, which are so extreme and which diverge so far from common doctrine that they can scarcely be reckoned as part of Islam, are the Druses; the Nusairites, or Alawites; and the Ali-ilahis.

Although the sectarian movements were not direct expressions of national traits they were nevertheless the forms in which national or economic opposition was frequently expressed. Among the Persians this opposition was expressed chiefly in Shiitism, while among the Berbers of north Africa it took on entirely different forms. The spread of Kharijite ideas as well as the success of the Shiite Idrisites and the growth of Almoravide and Almohade movements were considerably influenced by Berber reactions.

From the Shiites, who first acquired a Messiah, the concept of the Mahdi has been taken over in a modified form by the Sunnites. For them he is simply a descendant of Mohammed, who will fulfil the ideal of the caliphate at the end of time and carry on the tradition of the rightly guided caliphs. The figure of the Mahdi has gradually passed from the realm of politics to that of eschatology; nevertheless, the history of Islam is full of Shiite and orthodox Mahdi rebellions. In its expectation of the Mahdi orthodox theory has expressed most vigorously its condemnation of the entire political history of Islam since the first four caliphs. But the repudiation of any state not entirely dominated by religion was accompanied by the most far reaching toleration in practise. This departure developed under the constraint of actual conditions, particularly in the political field, and was nourished by historical pessimism and veneration for the inscrutable will of Allah. Thus one is expressly commanded to obey any ruler, even if he obtains and exercises power illegally.

The majority of Moslems have for centuries

considered the orthodox system and still regard it today as the only legitimate form of Islam. It embraces the entire religious doctrine of Islam and is the expression of both the religious consciousness of the Islamic community and its "catholic instinct." Even though certain views and customs were initially rejected with violence, once they had infiltrated a considerable section of the community they were acknowledged without difficulty as orthodox. Thus a person who held that an expression of the Islamic spirit which the convictions of the community had stamped as orthodox was inadmissible would himself be guilty of a breach of orthodoxy. The content of orthodoxy is identical with that of the universal agreement (*ijmā'*), which is considered infallible and upon which not only Islamic law but the entire Islamic religion is based. Its exponents are the theologians of every age, for Islam has no councils or other organs to establish the *ijmā'*. Its role is retrospective and confirmative; the *ijmā'* serves to legitimize innovations although it does not introduce them; it tolerates a certain evolution of Islam but at the same time keeps it within definite limits. Thus it has recognized as orthodox both moderate mysticism and the veneration of the prophet and saints. As the expression of the consciousness of the community the concept of orthodoxy is subject to fluctuations and cannot be delimited logically. The fundamental doctrines, however, are anchored in the community consciousness with particular firmness, even though they have never been officially defined.

The essential dogma of Islam is belief in the absolute unity of Allah, the creator of the world, who neither begot nor was begotten and whom nothing resembles. Allah causes all the actions of men as well as every happening in the world according to his eternal predestination. At the same time men are capable of free actions, for which they are rewarded or punished. Among the prophets accredited by miracles the last and most eminent was Mohammed; the others were Adam, Abraham, Moses, David and Jesus. In addition to the prophets there are the saints. The theoretical compromise by which orthodox Islam acknowledged the worship of saints, which was originally quite foreign to Islam and which came from the preexisting folk religion, was due to the religious needs of the masses of the people. Such a compromise was possible only after the figure of Mohammed, in contradiction to the Koran, had become en-

dowed with superhuman attributes. This process began at a very early date and was furthered by mysticism and by the popular belief in miracles. Since then the prophet has stood at the head of all the saints. Magic and amulets, which have religious sanction, form an important element of the popular world of ideas. The principal signs of the day of judgment are the appearance of the Antichrist, of the Mahdi and the return of Jesus. The day of judgment, with the prophet interceding for the members of his congregation, as well as paradise and hell are described in detail. The believer who commits grave sins does not necessarily become an infidel, and while unbelief is punished by eternal hell, heinous sinners who are believers will not remain in hell forever.

The chief religious commandments, the so-called "pillars of Islam," are five in number: the profession of faith (*shahāda*), the ritual prayer (*ṣalāt*), fasting (*ṣawm*), the payment of the alms tax (*zakāt*) and the pilgrimage (*hajj*). One becomes a Moslem by reciting the profession of the faith: "There is no god but Allah, Mohammed is the apostle of Allah." Circumcision although generally practised is not obligatory. The faith consists in belief and profession of the creed. Islam is decidedly a religion of laws and on the whole compliance with commandments is emphasized rather than "faith." The ritual prayer as distinct from the individual prayer has become the chief outward characteristic of the Moslem. It consists of movements of the body, recitations of the Koran and religious phrases and must be performed five times a day in the direction of the Caaba in Mecca. On Friday the midday *ṣalāt* takes place as a communal service under the leadership of a president (imam), who reads two sermons. Except for this, Friday is a day of work like any other. Fasting is obligatory from dawn to sunset during the month of Ramadan and involves complete abstinence from food, drink, perfume, tobacco and sexual intercourse. The alms tax, a sort of capital tax in kind, is levied once a year and its proceeds are supposed to be employed only for certain charitable purposes. It developed during Mohammed's lifetime from the earlier duty of giving alms and is a church and poor tax rather than a state tax in the western sense of the term. In addition private charity is warmly recommended and widely practised. Every adult Moslem is obligated to make a pilgrimage to Mecca once during his lifetime if he is able to do so. The duty to carry on the jihad, the holy war against unbelievers, was almost

accepted as a sixth pillar and has a wide popular appeal to the present day. It is based on the assumption that the relationship of the Islamic community to all non-Islamic communities is one of war, which may be interrupted by an armistice solely for reasons of momentary advantage and which ends only with Islam's subjugation of the entire world. As a reaction against the dominance of the spirit of battle in Islam's early days there was later developed the doctrine of the "great holy war," consisting of the struggle against one's own passions.

Islam has no clergy, no church organization and no liturgy in the true sense of the term. The theologians are merely those who know the divine law; they do not compose a real clerical caste. Nevertheless, they possess considerable influence, because the ordinary Moslem, even though it is impossible for him to live in accordance with the law, expresses his respect for it by the deference he shows its representatives. Orthodoxy moreover disputes the necessity of guiding the individual soul and dislikes the activity of the Sufite sheikhs, who play the roles of spiritual directors; nor can Islam acknowledge any dispensation of divine mercy through men.

Although like mediaeval Christianity Islam is a religion of the hereafter and as such has an ascetic element, it has not been able to suppress a characteristic elemental love of the world. The latter appears in the rejection of monasticism, in the natural respect for marriage and in the positive attitude toward trade and worldly goods. But in the main a spirit of renunciation prevails and is indicated by the warnings against woman, the prohibition of nudity, the repudiation of splendid buildings except as houses of worship, an economic ethics based upon religion, the condemnation of speculation in commodities and the praise of manual labor and of poverty. Other religious prescriptions are the frequently violated prohibitions of music and the portrayal of living beings and the absolute prohibition of wine and pork. The obligations to live simply and continently, to direct all activity with a view only to God and to bear up under misfortune arise from the feeling that one is a mere visitor in this world. The widespread fatalism of the Orient, however, is not based upon religion but is a matter of education and of temperament. The consciousness that all men are slaves of Allah is of great social importance, as is the strong feeling of religious brotherhood. Outwardly this corre-

sponds to a rigid separatism and a pronounced religious pride.

The political character which has marked Islam down to the present day is largely dependent upon the fact that Mohammed was not merely a prophet but also from the time of his migration from Mecca to Medina the undisputed secular leader of his congregation. During his Mecca period the spread of Islam as a religion was due solely to the prophet's religious energy and to the conviction of his associates. But during his Medina period emphasis was placed less upon conversion to the religion of Allah than upon submission to his prophet. Numerous conversions of individuals and even more so the conversion of entire tribes were of a political nature. With the spread of the religion of Islam Medina's hegemony was extended. This political structure upset the Arab tribal units by tending to make the acknowledgment of the prophet rather than membership in the tribe the distinctive criterion. Nevertheless, tribal feeling remained very strong and it was only Mohammed's personality that held the community together. The chieftains considered themselves bound only to Mohammed and after his death both the state and the religion were threatened with dissolution. Thereupon certain influential associates of the prophet succeeded in effecting the maintenance of the monarchical principle and under it one of them was chosen the first caliph; that is, the successor to Mohammed in all the latter's functions except the specifically prophetic. The political leaders succeeded in focusing the lust of the various tribes for booty upon a common goal, the holy war for the spread of Islam. The extensive development of the doctrine of the jihad at an early period indicates that the spirit of battle was fostered at the expense of everything else.

The expansion of the Islamic state cannot, however, be attributed to religious enthusiasm but must be explained rather in terms of the great migrations of peoples who time and again spread from Arabia to the surrounding civilized countries. This was the last of such migrations. Because of economic and political conditions in Arabia the tribes had been in a state of unrest for centuries before the advent of Mohammed. Islam united them. The religion made possible the political organization of Medina, so that a state grew out of a congregation. Later, however, it was the state and not the congregation that employed the Arab migration, which had begun independently of it, for its own political

aims. The surprising success of the Arabs is explained by the combination of a program which unified the nation, the will to power of a young state led by eminent men and conditions in the Persian and Byzantine empires, which practically invited conquest. The soldiers were stimulated by their share of the booty, four fifths of which was divided among them.

The thirty-year reign of the four first caliphs, abu-Bekr, Omar, Osman and 'Ali, all associates of the prophet and members of his tribe, was later looked upon as the golden age of Islam. It marked the first great stage of the expansion of the Arab-Islamic state, which took place under Omar and Osman and during which Syria, Iraq, Persia and Egypt were conquered. But already tribal and personal dissensions were making themselves felt. Disturbances under the reign of Osman resulted in the assassination of the caliph. The new caliph, 'Ali, was engaged in continuous battle with his opponents, the most formidable of whom was Mu'āwīya, a relative of Osman, who claimed the caliphate himself; but before the struggle against Mu'āwīya had been decided 'Ali was assassinated and Mu'āwīya obtained general recognition as the first of the Ommiad caliphs.

Under the Ommiads, during the second stage of Arab-Islamic expansion, Armenia, Transoxiana, Afghanistan and the Indus area were subjugated in the East and north Africa and Spain in the West. As a result large areas of the Christian world came under Islamic rule. Their Islamization and that of other conquered territories did not, however, keep pace with their subjugation. As long as Islam remained confined to Arabia, the overwhelming majority of the adherents of the new state accepted its religion no matter how superficially. But as soon as the civilized countries of the Near East and north Africa were conquered, the expansion of the Islamic state was sharply differentiated from that of the Islamic religion. With certain exceptions the Arabs did not want to convert the vanquished but desired rather to maintain themselves as an upper class with special economic privileges above the masses. The nationalist Arab factor tended to outweigh the universal religious factor and the Arabs did not attempt to press their religion upon the Near East at the point of the sword. Believers in scriptural religions who submitted to the conquering Arabs were given protection and retained the freedom to exercise their religion upon payment of tribute. At an early date the concept of privileged

religions based upon scriptures was extended beyond Judaism and Christianity to include practically all important beliefs with which Islam came in contact; only the extinct Arab paganism was excluded. The *dhimmi*, or non-Moslem subject, was a citizen with lesser rights, whose most important disability was that he was not privileged to appear as a witness in an Islamic court. The tribute (*jizya*) paid by the *dhimmi* and the *kharāj*, a tax on the conquered lands left in the possession of their former owners, became the chief source of income of the state Treasury. Pensions were paid from it to the fighting Moslems and their families, varying according to their station in the theocracy. Because religion and government were then essentially Arabic in character the conversion of non-Arabs was possible only by means of affiliation with the Arab tribes. Non-Arab Moslems inherited the position and the name (*mawla*) of the tribe's foreign associates. The spread of the Islamic religion within the Arab-Islamic empire signified the growth of the ruling class and a decrease in the number of tributary subjects, for the payment of tribute ceased with the acceptance of Islam. Hence Islamization was not even desired and was certainly not an end in itself. Nevertheless, the ruling class could not but exert an ever increasing attraction if the vanquished could rise to its level and merely by changing their religion insure for themselves considerable economic and social advantages. To forbid conversion was to contradict the religious tendency of Islam, and ultimately the idea of the universal religion overcame the national principle of a state which had originally been identical with this religion. During the closing period of the Omniad empire an endeavor was made to reconcile increasing Islamization with this national principle, partly by means of a reform of taxation which greatly reduced the economic incentive to conversion.

Alidic propaganda, supported by other factors, such as the dissatisfaction of the *mawla*, finally led to the downfall of the Omniads in 750. But it was not the Alides, the descendants of the prophet, but the Abbassides, their cousins, who succeeded to power as a result of the revolution. Using the Shiite propaganda for their own ends and carrying on intensive propaganda of their own they pushed the Alides aside and their victory marked the end of the Arab kingdom of Islam. A member of the destroyed dynasty succeeded in founding an independent kingdom in Spain, which later developed into the

caliphate of Cordova. Like the caliphate of the Abbassides it was orthodox in religion and was opposed to the latter only in the political field.

During the first century of the rule of the Abbasside dynasty the social differentiation based upon nationality vanished entirely. When the Arabs entered into closer contact and economic competition with the native populations, the latter proved themselves far superior both materially and intellectually. To this superiority the Arabs were able to oppose as their own distinction only their religion, which was therefore strongly emphasized. The government was characterized by oriental despotism with all its auxiliary manifestations, instead of by the Arab aristocratic form of rule. There was no longer a ruling people dominating the vanquished but one mass of slaves on the same footing under a master. With the completion of the process of social leveling the Arabic language and with it the religion spread at a faster rate. At bottom the Arabs had been but little interested in religion; the new converts or their descendants, who possessed quite different religious traditions, now began missionary work. With despotism there also entered the concept of a state church, which had been quite foreign to the Arabs despite the emphasis upon their own religious superiority. The conversion of the non-Moslems now lay in the interest of governmental authority, to which religion became a necessary prop. The rulers endeavored to obtain the support of the theologians, and the latter fired by religious zeal began to work intensively for conversion. As a result the caliph's empire was extensively Islamized.

In the unified near eastern state represented by the Omniad-Abbasside caliphates there developed upon a Hellenistic basis an integrated civilization with Arabic and an increasing number of Asiatic traits showing the influence of all the various countries involved. Islam then permeated both state and civilization, impressing them with a unified religious stamp. At the same time Islam entered upon its close link with a definite ideal of the state and a culture that characterized its future, while in turn it underwent considerable changes as a result of the assimilation of the spiritual heritage of former religions. This occurred as much externally, through religious discussion with its resultant borrowings and its polemics, as it did inwardly, because the converts from other faiths simply continued within Islam their former religious life with its customs, interests and problems.

Now for the first time Islam became a combination of a religion and an ideal of a state and of a civilization; and despite all local peculiarities and political splits it formed a great spiritual unit reaching from the Atlantic Ocean to China. The religion did not create the state and the corresponding civilization, but Islam as a whole arose from the combination of these three factors. Later, when the state and the civilization decayed, their ideal based upon religion remained a part of Islamic doctrine.

After a century of brilliant splendor the Abbasside empire began to break up in a way that has been characteristic of all great Islamic states. The weakening of the centralized government led to the political autonomy of the provinces under practically independent rulers and dynasties. At the same time the latter endeavored to legitimize themselves by establishing a relationship of mutual recognition with the caliph; he invested them with the administration of the areas over which they ruled and in return he was acknowledged as overlord. Thus there arose the differentiation between the caliphate and the sultanate, which dominates all later Islamic history. Besides the Omniads in Spain it was principally the Fatimites in north Africa and Egypt who refused to recognize the supremacy of the Abbassides and set up in opposition a caliphate of their own, the most significant political expression of Seveners. The founders of the Fatimite dynasty were closely linked to the religious-social movement of the Karmatians, a movement which was stimulated by the contemporaneous slave rebellions and which temporarily developed a type of communist society. Like the Ismaelite movement, with which it was originally connected, it had political and social revolutionary aims, which its leaders endeavored to realize by means of a vast conspirative activity within a hierarchical organization, in which the subordinates were completely under the spiritual and moral rule of the master. Ultimately the Fatimite caliph al-Ḥākim claimed to be the incarnation of God Himself. Some twenty years before the rise of the Fatimites another Shiite state had arisen in Morocco with the establishment of the kingdom of the Idrisites.

In the eleventh-century there was a reaction directed against the political dismemberment and the threatened religious dissolution of Sunnite Islam, and for a time religious and political unity were restored both in the east and in the west. In the west this unity was achieved

by Almoravides, who were soon succeeded by the Mahdist movement of Almohades. The latter in turn departed from pure orthodoxy in their very strict enforcement of monotheism and in the magnification of the Mahdi's attributes. In the east the reorganization of Sunnite Islam was the work of the Seljuks, who like the Abbassides were the chief exponents of the old Persian concept of the state with its official religiosity embodied in Islam. They parceled out most of Mesopotamia, Syria and Asia Minor in military fiefs, which toward the end of the twelfth century were practically independent. After the Seljuks had been greatly weakened by the First Crusade, their role as champions of Islamic orthodoxy was taken over by Saladin, who put an end to the Fatimite caliphate of Egypt, and his Ayubite dynasty. From Islam's point of view the crusades were a mere episode. Shortly thereafter the entire eastern Islamic world was deluged by the Mongol conquest, which came to a stop only at the frontier of Egypt and which destroyed the caliphate of Bagdad together with numerous smaller states. Sultan Baibars, the most eminent representative of the Mamelukes in Egypt, who had succeeded the Ayubites there, gave shelter to an alleged member of the caliph's house; and from that time the caliphate was practically only an office in the court of the Egyptian sultan, whose occupants exercised the function of granting their sovereigns a formal investiture. The hopes which the Christians centered in the Mongols were rendered vain by the latter's conversion to Islam, which penetrated the new Mongol states with unexpected rapidity.

Upon the ruins of one of the little Seljuk states which continued to exist in Asia Minor as Mongol dependencies the Ottoman state developed, struggling continuously against the Byzantines. Warriors' leagues established upon a religious basis played a dominant part in its foundation. It recovered with astonishing ease from the blow dealt it by the Sunnite Turk Timur (Tamerlane), who for a time united politically most of western Asia. About 1500 the Shiite Twelvers also found their political center, which has persisted down to the present, in the Alide family of the Safawides in Persia. The new dynasty, which reached its pinnacle a century later, energetically opposed the Ottomans. The intensification and embitterment of the conflict between the Sunnites and the Shiite Twelvers dates from this period of religious and political struggle. The third great Islamic em-

pire of modern times, that of the Moguls in India, which also arose about 1500, experienced a period of brilliant splendor during the sixteenth and seventeenth centuries, then declined steadily until its last shadow vanished in 1857. The Ottomans continued to spread in Europe and Asia and with the conquest of Egypt and the holy places gained undisputed predominance in Sunnite Islam. At the time of its greatest extent in the early sixteenth century and even later the Ottoman Empire restored the political and religious unity of Islam to a considerable degree and the claim of the Ottoman sultan, as the most powerful Islamic ruler, to the caliphate was widely acknowledged. Among the Ottomans Islam is characterized by the synthesis of strict orthodox dogma and a strongly mystical piety with a certain Shiite cast. The Ottoman advance made an even stronger impression upon Christendom than had the initial expansion of Islam. But the serious even though essentially temporary losses of the Christian world resulted neither in the defeat of the modern occidental civilization, which had developed in the interval, nor in a decline of the Christian religion comparable to the Islamization of western Asia and north Africa.

Islam extended beyond its political boundaries mainly through trade channels as a result of its cultural superiority over primitive peoples. Both within and without the Islamic state the spread of the new religion took place as a rule peacefully and naturally; conversions by force and persecutions, which are contrary to the spirit of Islam, were comparatively rare. The same factors account for the peaceful expansion of Islam as for its strong hold over those whom it has once converted. Because of the absence of a clergy and of any ecclesiastical organization the feeling of responsibility rests upon the individual believer. Accordingly he tends to give his religion an important place in his life and is unusually energetic in his endeavors to spread it. Not only the religious teachers, who devoted their lives to this task, but all classes of the Moslem population participated actively in the propaganda for their faith, particularly the merchants, who had many opportunities and who were not subject to the distrust with which primitive peoples often regard the foreigner and the professional missionary. Chief among the inherent qualities of Islam which have aided its successful expansion are the simplicity of its principal dogma of the unity of Allah and of his relation to the prophet Mo-

ammed and the rationalist nature of the entire doctrine. The eschatological factor, the strong emphasis upon the hereafter, and most of all the fearful threat of the punishment of eternal hell for unbelievers are also effective. Then there are the simple and definite religious obligations, among them the ritual prayer, which must be recited five times a day by the believer; and the pilgrimage, which represents an imposing and inspiring manifestation of Islamic unity. Another factor contributing to the strength of Islam is its ability to assimilate folk beliefs as well as its theoretically tolerant, syncretic attitude toward the earlier revealed religions. These tendencies have been aided by certain external circumstances: in most of its missionary fields Islam appeared as the religion of a ruling class, of a powerful state and of a fascinating civilization; it insured a rise to a higher social and cultural status and often attracted the more progressive elements of the population. The pious life of its believers, which becomes a permanent missionary message, and the virtues attendant upon it made a profound impression, even upon the Christians at the time of the crusades and the wars against the Turks. The various movements for religious reform in modern times have reenforced the missionary activity of Islam.

During the past fifty years there have been endeavors at reform through the further development of Islam. One of these was made by the Ahmadiya, founded in the 1880's and since become a separate sect. Its founder, Mirza Ghulam Ahmad, claimed to be a returned Jesus as well as the Mohammedan Mahdi; repudiating the holy war he addressed his preaching to Moslems, Christians and Hindus. The more moderate of the two schools which later developed from his doctrines had its seat at Lahore and devoted itself to intensive missionary work in India, in Moslem Africa and in Europe, where it gained adherents chiefly in England and Germany. Despite the endeavors to ally itself with Sunnite Islam it is rejected by practically all the schools. More important for the development within Islam has been the modernist movement.

In Asia the territory of the Moslem state was Islamized at a relatively early date; only later, with the rule of the Seljuks and Ottomans, did the religion penetrate Asia Minor as well. Large areas in India were added in the eleventh century. Islam had reached China even earlier, through Turkestan, Islamized from Transoxiana, and by the ocean route. The Mongol move-

ment resulted in larger gains in China. The Malay islands were Islamized from India and later directly from Arabia. Islam also gained adherents in the Philippine Islands. The northern coast of Africa was conquered at an early date and through trade Islam penetrated beyond the borders of the empire into north and central Africa, starting from Upper Egypt and Morocco and passing along the oasis routes of the Sahara. After about the ninth century this was supplemented by an Arab settlement and the Islamization of the Zanzibar coast as far as Madagascar. Islam also gained a foothold in western, southern and eastern Europe, but was completely driven out of Spain in the fifteenth century. The appearance of the Normans turned the tide in southern Italy and the Mediterranean islands, which had been conquered and Islamized from the African shores. In the east the Ottomans carried their religion as far as Hungary and Greece, but it gained a firm footing only in the Balkan Peninsula. In Russia it was spread chiefly through the Mongol movement; the Islamization of the Golden Horde was a great victory; the Kirghiz were converted to the Islamic faith in the eighteenth century by the Russian government, which regarded them as backward Moslems.

From the end of the seventeenth century the great Islamic empire of the Ottomans fought a losing battle with the west. During the nineteenth century the process was greatly accelerated, but until the beginning of the twentieth century the military and political defeats of Turkey in Europe resulted neither in a weakening of Turkey's position in the Islamic world nor in a reorientation of the religious-political forces within Islam. On the contrary, these defeats led to the promotion, particularly by Abdul-Hamid II, of a defensive movement known as pan-Islamism (*q.v.*), which was directed against Europe and which aimed at strengthening and expanding the traditional Islamic religious and political unity. The impact of the West tended, however, to create more particularistic nationalist movements, which after 1900 became popular and spread extensively among the peoples of the Near East. Among the Ottoman Turks nationalism temporarily took the form of pan-Turanism, a tendency toward union with racially allied Turkish peoples. As a consequence of the World War nationalist sentiments aided by foreign propaganda developed enormous strength. After the war the new Turkish government, although confined to Turkish

territory, carried nationalism to its logical conclusion and effected a complete break with the Islamic cultural past. Religion was eliminated from public life and was subordinated to the interests of the state. The sultanate was abolished in 1922; this was followed in 1924 by the abolition of the caliphate and in 1928 by the abolition of Islam as the state religion. The orders of dervishes were also suppressed. Among the Arabs, however, the nationalist movement, which led to the downfall of the Ottoman Empire, has entered into a union with Islam, conceived as a religious and spiritual force, while repudiating religious fanaticism. Arab nationalism is local in its nature and consists of Syrian, Iraq and other local movements; for the moment it has renounced political pan-Arab ambitions. The disappearance of the caliphate has furthered the idea of international religious congresses in Islam but not of a pan-Islamic movement in the proper sense. Thus the end of the political evolution of Islam is marked by the renunciation of the practicability of the political ideal; despite the political disintegration of the Islamic area and the abolition of the caliphate, however, a strong common feeling exists against European domination, although without any serious threat of a holy war.

At the present time the religious aspect of Islam has again become the most effective; the bonds between Mohammedans are based upon their common faith and the unity of their ideals. With the modernization of public education traditional theological training is declining, but a greater revival of actual religious activity is being manifested. The mark of real Islamic unity is the common acknowledgment of the Koran, which although losing some of its dominion is still venerated and upheld by the people. The movements of modernism and nationalism which have arisen under the influence of occidental ideas involve a new and profound change in the cultural environment of the Moslems affected by them. Under their influence the political and cultural elements of the Islamic ideal are beginning to be consciously abandoned and to be replaced by modern occidental ideas. Even the traditional forms of the religious ideal are being measured by critical standards. This retreat to the real religious domains of Islam, which to its advocates seems to be a return to what is original and basic, may revive its central religious forces, which are still energetic, and thus offset the losses sustained by Islam in the political and cultural fields.

A modernist wing has arisen, with its principal centers in India, Egypt and Turkey. Common to all of its tendencies is the realization that Islam has stood still for centuries and is in need of a renaissance. Opinions differ as to how this is to be brought about. Many nuances of opinion are represented: from an absolute lack of understanding of the spirit of the west to its complete adoption; from an almost Wahhabite traditionalism to the flat rejection of Islamic law; from the attribution of all modern achievements to the Koran and the Sunna, to a critical insight into the history of Islam. Behind these trends is the thought that the real Islam is not hostile to civilization but on the contrary looks with favor upon progress; that the true core of the religion must be freed from the human structure which has been superimposed upon it, and which is responsible for Islam's decline; and that Moslems are entitled to take an unfettered stand upon modern problems with a view to the common good. From this there follows the rejection of the orthodox system and the endeavor to reduce Islam to a core of religious-ethical truths. The tendency to base the interpretation of the Koran and of those traditions which are acknowledged as genuine upon modern ethical and social ideas usually leads to views which are historically incorrect. Even within the most narrow orthodox groups there is an unmistakable striving for a religious revival. The various currents, which in part overlap one another, are the expression of the present crisis in Islam. It is quite possible that Islam will be even further differentiated—through the formation of national churches rather than by the rise of sects. It is to be expected that the mass of the population will cling to its traditional forms, while modernism will continue to spread among the educated. But the advance of modernism will not mean any weakening of religious convictions and it is very unlikely that the present grave crisis, marked by the conflict with western ideas, will destroy Islam.

According to estimates made in 1929 Islam has about 246,000,000 adherents, of whom 64,000,000 are Indians, 51,000,000 Malays, 38,000,000 Arabized races including 12,000,000 pure Arabs, 34,000,000 Turks, 26,000,000 Iranians, 23,000,000 Negroes, 7,000,000 Chinese and 3,000,000 members of Balkan nationalities. Only about 50,000,000 are formally independent of western powers, including Egypt (12,800,000), Turkey (13,000,000), Persia (9,000,000), Afghanistan,

Arabia and China. From a study made in 1923 it appears that at that time more than 90,000,000 Moslems were under British, 39,000,000 under Dutch and 32,000,000 under French rule in colonies, protectorates or mandated territories. There are over 15,000,000 in Russia. The vast majority of Mohammedans inhabit Asia and Africa; in Europe they are confined to Russia and the Balkan Peninsula; while in Central and South America they total about 193,000, and in the United States, including the Philippines, about 598,000. Sunnites constitute 91 percent, or 223,000,000, of all Moslems, while 8 percent, or 22,000,000, are Shiites; of the latter 1,000,000 are Zaidites and 17,000,000 Twelver Imamites. There are about 1,500,000 Ibadites. At the present time the number of Moslems is increasing principally in the countries which have been or are now under European rule and is stationary in the rest of the world. There is no apparent expansion of Islam into new fields, but the decline noticeable in Central Africa, India and the Dutch East Indies is very slight. No reliable data are available on the situation of Islam in the Soviet Union. Islam still exerts attraction as a social force. The majority of the new converts come from the "colonial proletariat," who through Islamization obtain civil recognition and the consciousness of human dignity; for most Mohammedans do not look upon their community as merely a juridic unit but as the ecclesiastical and almost ontological reality of a society of supernatural origin.

ISLAMIC LAW, called *Shari'a*, embraces all of Allah's rules for the conduct of man. It is supposed, however, to govern only the external relations of the Moslem to his fellow men and to Allah as distinct from the individual's conscience and feeling of religious responsibility. Since Islam has been from its beginnings a political entity as well as a religion, its law is theoretically an infallible doctrine of moral obligations encompassing without limitation not only the entire religious and domestic life of believers in Islam but also their political and social activity. Alongside prescriptions governing religion and ritual duties it comprises equally authoritative rules of a juridical and political nature and provisions for matters of all kinds, such as legitimate and prohibited musical instruments, sexual intercourse, archers' matches and racing, the portrayal of living beings, clothing and adornment. Islamic law, which evolved historically as the result of the combination of several factors, is a col-

lection of precepts rather than a system based on broad general principles in the western sense; it demands that its adherents accept it as inscrutable wisdom without criticism. The chief tendency in its evolution was the religious evaluation of all the conditions of life; juridical considerations were secondary. The *Shari'a* is a typical example of sacred law in a religion based upon prophetic scriptures and hence it is specifically jurists' law, a product of scholastic doctrine dominated by casuistry. It is of a non-formal character, since it does not aim at regulating conflicts of interests but at enforcing material postulates of religious ethics. Chiefly because of the close fundamental relationship between state and religion the theocratic link between religious-ritual duties, legal norms and moral admonitions could not be dissolved. The *Shari'a* differs from the canon law of the Middle Ages in that the latter was much more rationally developed and much more formal from the juridical standpoint. In the canon law rational precepts under centralized authority took the place of interpretative evolution, while secular law stands alongside the canon law with a clear distinction between their spheres of authority.

The prophet Mohammed did not intend to establish a system to regulate the entire life of his adherents. On the contrary, during his lifetime there continued to exist as a matter of course the old Arabic customary law, which although based mainly on Semitic tribal law was considerably modified in the course of adaptation to different social conditions (e.g., the commercial law of Mecca, the agricultural law of oases like Medina) and contained numerous foreign elements of provincial Roman and perhaps Iraq and south Arabic origin. Mohammed confined himself to the issuance of various religious-ritual and military-political prescriptions and to the modification on religious grounds of the law on individual questions—inheritance, for example—as they arose. This was not always done through the Koran; important sections of religious legislation, such as the ritual of divine service, and various separate points were settled simply by the prophet's example and command. With his death this Koranic and extra-Koranic legislation ceased. The first few caliphs endeavored in agreement with the most distinguished associates of the prophet to direct the community as its founder desired; but they nevertheless considered themselves empowered to enact legislation upon their own authority and when advisable they even changed the decisions

of Mohammed. The relationship between the Islamic legislation and the customary law remained the same as before, even after the latter had been increasingly exposed to foreign influences as a result of the vast conquests. This was absolutely inevitable, for in the conquered territories with their more complex civilizations the law which the Arabs brought with them proved inadequate and frequently inapplicable. At the same time legal practise was being continually developed and modified by decisions of Moslem administrators and judges.

With the rise of the Ommiad dynasty and the transfer of the capital to Damascus the pious circles of the former capital, Medina, lost their influence upon the government and began to construct an ideal picture of what conditions should be in contrast with actual circumstances, trying to systematize the existing legal material and to infuse it with Islamic religious principles. It was this group which laid the foundations of Islamic jurisprudence (*fiqh*). To emphasize the authority of Medina they gave particular weight to the sayings and actions of their predecessors, Mohammed's associates, especially to majority decisions. This deference to majority opinion (*ijmā'*) favored the development of common doctrine and the elimination of isolated viewpoints. The results of this speculation were largely formulated into traditions and attributed to the prophet himself. In this process many new elements, especially those of Jewish origin, were again introduced. The beginning of Islamic law already reveals some of its characteristic features—its interpretative nature, the restriction of legislative activity to the prophet, the acknowledgment of Mohammed's real or fictitious practises (Sunna) embodied in the traditions as the principal source of law in addition to the Koran. The customary law was still recognized as fundamental.

The earliest theoretical disputations occurred during the first half of the eighth century over the role of the activity of the human mind (*ra'y*) in jurisprudence. They ended with acknowledging the *ra'y* in principle, the various schools of opinion giving the traditions more or less weight. Toward the middle of the eighth century special tendencies in jurisprudence were evident in the spiritual centers, Hejaz and Iraq. The chief representative of the Hejaz school, Mālik ibn-Anas (d. 795), acknowledged the Sunna of Medina as authoritative and devoted much care to determining the content of *ijmā'*, which he defined as the decisions of an almost

unanimous majority of the learned men of Medina. His doctrine represented the final Islamization of juridical material achieved at that time. Al-Shaybānī (d. 804) personified a corresponding stage of evolution for Iraq.

But the founder of Islamic jurisprudence as a Mohammedan science was al-Shāfi'ī (d. 820), who did not limit his argumentation to special occasions or to single decisions but established definite principles. Moreover he investigated the points of departure and the methods of juristic argument themselves. He finally fixed the concept of the Sunna as meaning the prophet's own practises. He explained the *ijmā'* as the opinion of the majority of all Moslems and employed it as a source of law supplementary to the Koran and the Sunna. He also did much to advance the systematization of legal material but departed to some extent from the path of building up juristic concepts, in which a start had already been made. Rather he developed principles for the use of analogy (*qiyās*) and employed them extensively; analogy was in essence the old method of the *ra'y*, for which al-Shāfi'ī endeavored to establish definite norms. He had but little success in this, however, and the methodology for employing the *qiyās* has remained indefinite. Al-Shāfi'ī rejected a variant of the *ra'y*, the so-called *istihsān* (the departure from analogy upon grounds of equity and other grounds), because he regarded it as purely subjective.

After the great personal achievement of al-Shāfi'ī had led to the establishment of a Shafite school, the older principal trends of opinion were also forced to organize into definite schools. Typical representatives, such as abu-Ḥanīfa (d. 767) in Iraq and Mālik in Hejaz, were acknowledged as the heads of these schools. Finally the old traditional wing, which viewed all speculative extension of religion with suspicion, also organized itself into a school of law named after ibn-Ḥanbal (d. 855). These are the four Sunnite schools which have persisted down to the present day; others which arose at the same time or later are now extinct. The non-Sunnite communities of Moslems have their own systems of *fiqh* which, however, have been strongly influenced by Sunnite jurisprudence; although based on different principles their peculiarities are no greater than those distinguishing one Sunnite school from another. The most important of these communities, the Shiites, recognize as their main source of law in addition to the Koran the Sunna of the prophet and of his successors, the imams, the chief among whom was the

caliph 'Alī. All religious doctrine is traced by means of traditions to their paramount authority. Only in the absence of the last imam—who is hidden—is the community guided by the learned interpreters of the law, the *mujtahids*. They are authorized to draw conclusions from the Koran and the Sunna by using the human reason (*'aql*); their unanimous opinion (*ijmā'*) is considered valid.

There are no fundamental differences between the orthodox schools. They all recognize the same principles of law and differ merely in their application; their juridical thinking and the results achieved are practically alike. They recognize each other as orthodox and as of equal authority; mutual intolerance has always been disapproved by their authoritative representatives. The school of the Zahirites, founded by Dā'ūd (d. 883), rejected all *qiyās*, acknowledged *ijmā'* only in so far as it had been reached by the prophet's associates and insisted upon being guided solely by the literal interpretation (*zāhir*) of the Koran and the Sunna. It did not, however, exert any permanent influence. The spread of the various schools was determined chiefly by secondary factors, such as the influence of their representatives, their geographical location and the attitudes of rulers. Today about 30,000,000 Moslems in Upper Egypt and the Sudan, north and central Africa are Malikite; this school also predominated in Moslem Spain. There are approximately 118,000,000 Hanifites in Turkey, central Asia and India and areas formerly under Ottoman rule. Lower Egypt, east Africa, western and southern Arabia, the coastal regions of India and the Dutch East Indies are Shafite, embracing some 73,000,000 adherents. Perhaps 3,000,000 Hanbalites are found in central and eastern Arabia.

The establishment of the schools of law represented the end of the creative periods of the *fiqh*; only details were increasingly elaborated later on. Evolution after al-Shāfi'ī, while recognizing the Koran, the Sunna, *ijmā'* and *qiyās* equally as the four roots (*uṣūl*) of *fiqh*, emphasized the Sunna at the expense of the Koran, which could be modified by the former. The *ijmā'*, in the sense of the agreement of the learned men of any period, came to be regarded as infallible and binding for the entire future. Originally a mere supplement to the Koran and Sunna, it thus evolved into an instrument for their confirmation and even for their abrogation, as when it permitted the worship of saints and introduced the doctrine of the prophet's personal infalli-

bility. Important portions of the law—the caliphate, for example—are based solely upon this *ijmā'*. In the last analysis the entire system of the *fiqh* owes its authority to the *ijmā'*, which vouches for its correctness and for its agreement with the true meaning of the divine sources. Although the *ijmā'* really procured official recognition for important elements of practise, its significance as a source for progressive development in Islamic law should not be overestimated, since it is at least as likely to hinder as to aid the introduction of new ideas. Unsuccessful attempts have been made to add '*urf*'—that is, general usage—to the other four foundations of the *fiqh*. Theoretically the customary law is not acknowledged as binding even when the *fiqh* affords no rule. Despite the fact that the influence of customary law and of foreign legal practise, although not of foreign legal theory, was very important and was taken for granted in the early period of Islamic law, their further infiltration grew extremely difficult after the acceptance of the concept of the *uṣūl* in its final form.

The formal systematization of the legal material was ended by the eleventh century. The works of that period mark the high point for the evolution of juristic concepts. Subsequently casuistry again achieved undisputed predominance; and Islamic law grew more and more inflexible. In the early period and down to the tenth century a knowledge of the *Shari'a* could be obtained directly by a study of the Koran and tradition. Later, however, there prevailed among the Sunnites the conviction that nobody was authorized to undertake an independent examination of these sources by personal effort (*ijtihad*) but that all are bound to the unquestioning acceptance of what the preceding authorities have regularly established as the law (*taqlid*). Thus the *Shari'a* is authoritatively represented to the later generations by the system of *fiqh*, elaborated to cover most trifling details, whose authority rests ultimately on the infallible *ijmā'* of the community. These doctrines have not gone unquestioned. They are denied by the Shiites. The Wahhabites, who arose in the eighteenth century out of a much older trend of thought within the Hanbalite school, reject them and restrict the *ijmā'* to the agreement of the prophet's associates. As a result there were important departures in doctrine, with the purpose of restoring those of original Islam. But like the traditional system the Wahhabite soon reached the stage where further development was impossible.

The first significant theoretical incursion into

the *fiqh* system is that effected by the recent modernist movement, which does not acknowledge the *fiqh* as binding, since it is only the product of the human mind, and which considers it now obsolete as the expression of a prior epoch. It proposes instead to revise Islamic law in conformity with new ideas, on the basis of the most modern interpretation of the Koran and with a corresponding critique of traditions, maintaining at the same time that it attempts a return to the true principles of Islam. The modernist movement in Egypt has quite recently gone beyond a general criticism of the *fiqh* system to the creation of a family law in which an attempt is made to justify formally, by older authorities of the *fiqh*, materially radical innovations. After having been denounced at first as unorthodox the modernist movement is now struggling with an increasing measure of success for recognition within Islam; it promises, in its own sphere of influence, a development of those parts of Islamic law which still retain practical significance. But by their very nature both *Shari'a* and *fiqh* are hostile to change. Learned jurists are the strongest conservative element in Islam and in spite of the successes of modernism the spiritual power of the traditional *Shari'a* throughout Islam must not be underestimated. It is a great educational factor and has always been studied most diligently. In most circles it is still considered the sole subject of true learning, despite the warnings of the religious against exaggerating its importance.

The evolution of the *fiqh* as a progressing interpretation of the sources of law, with legislative activity theoretically confined to the prophet, has resulted in the absence of a real codification of the law in the modern sense. But each school of law has its own authoritative *fiqh* works and these have actually become the codes of the orthodox Moslem. In them he finds the *Shari'a* expounded in the form binding upon him in accordance with the doctrines of that school to which he belongs. Since not everyone is capable of using the books of the *fiqh*, laymen generally require instruction by experts. This is done by means of *fatwa* (opinion, information) handed down by savants called mufti. The "codifications" compiled by Moslems influenced by European ideas, of which the most famous is the Turkish *Mejelle*, are not intended to replace the volumes of the *fiqh* even where they possess official character but have been worked out in order to make the latter's contents more accessible to the layman. The codifications which have been

planned or carried out by European authorities cannot be considered as representative of the pure *Sharī'a* if only because of the innovations in their content. The French project for Algeria is the best known.

According to their traditional, unsystematic arrangement, the books of the *fiqh* devote the first chapters to the five principal religious-ritual obligations: ritual purification, divine service (*ṣalāt*), the alms tax (*zakāt*), fasting and the pilgrimage to Mecca. This is usually followed by contracts, inheritance law, marriage and family law, criminal law, the holy war (*jihad*) and relations with the unbelievers in general, dietary laws, sacrificial and slaughter regulations, oaths and vows, court procedure and the freeing of slaves. Not all of these involve obligatory prohibitions or commandments; in many cases it is merely advisable or reprehensible from the religious standpoint to omit or to do something. Finally, the law also regulates actions which it leaves open as permissible or neutral. Thus actions fall into five classes. This religious valuation has largely superseded the juridical categories proper.

The *Sharī'a* never succeeded in translating its claim of absolute validity into practise. It arose essentially as a protest against reality and as the delineation of an ideal, which was looked for only in the bygone early period of Islam and the return of which could be hoped for only under the Mahdi in the indefinite future. As the pious, who laid the foundations of the *fiqh* under the Omniads, were not bound by actualities, the doctrine of obligations evolved by them became largely incompatible with actual practise. After the failure of repeated endeavors to put the *Sharī'a* into practise, of which the most notable example was the attempt under the first Abbasides who accorded much influence to the jurists, the pious yielded to the conditions of the time. They obeyed state regulations, retaining, however, full freedom to voice their theoretical criticism. In theory the state acknowledged the *Sharī'a* and the learned men as its interpreters, but although it claimed no right of legislation upon the basis of the *Sharī'a* in practise it ignored the latter whenever it saw fit. Since all Moslems could not avoid violating the law continually, this state of affairs had to be accepted as willed by Allah; and savants went so far as to declare that it had been foretold by the prophet. The *Sharī'a* itself enjoins the acknowledgment of the de facto ruler and the doctrine was developed that necessity transcends the laws. In

situations where conditions made the *Sharī'a* difficult to observe ways were found to elude its provisions. An evasion of the prohibition against interest was taken over from the mediaeval West under its Arabic name, *mohatra*. The cadis, whose authority deriving from the *Sharī'a* had to be recognized by the government, found their competence gradually curtailed. In this way the law in so far as it was not workable eliminated itself from legal practise, although theoretically it could not accord recognition to differing legal customs but must at best suffer them in silence. Nevertheless, there was no sharply defined boundary between the theoretical system and the state power. This is shown most clearly by legal documents and by the office of the cadi, who was a state official as well as a judge on the basis of the sacred law. Eventually there remained under his jurisdiction only public worship, marriage, personal law, inheritance and in part pious endowments (*waqf*), all of which are in the popular consciousness closely connected with religion. The *Sharī'a* never really applied to the field of commercial law, even though practise endeavored to avoid violating in form such fundamental provisions as that which forbade the taking of interest. The secular powers increasingly assumed jurisdiction in matters of constitutional, criminal, military and taxation law as well as the more important property cases. This led to separate legislation alongside the *Sharī'a*, of which the best known example is the Ottoman *Kanunnames*, and resulted in codes along European lines, as in Turkey since the epoch of the *Tanzimāt* and more recently in Egypt. Thus throughout Islam there has arisen a twofold administration of justice, the religious and the so-called secular, quite independent of western influence.

Periods of the more or less correct observance of the *Sharī'a* have alternated with epochs in which it was violated or totally ignored. The last great wave of its observance began with the rise of the Ottomans. In practise the *Sharī'a* is everywhere observed solely because and in so far as it has become customary to do so. The stricter or more lax observance of the law bears no relationship to the degree of religious intolerance; nor is it always the theoretically most important obligations which are complied with, but rather those customs through which the Moslems differentiate themselves from the followers of other faiths. Even in marriage, family and inheritance law the *Sharī'a* is restricted by the *'āda*, the customary law. In the Dutch East Indies the

'*ada* is even theoretically recognized, outside of theological circles, upon the same footing as the *Shari'a*. In British India and in general throughout the Mohammedan areas under British administration the application of the *Shari'a* in its restricted sphere has been influenced noticeably by special rules of judicial procedure as well as by British legal thought. In Turkey the last stage of the influence of the *Shari'a* on commercial law had been marked by the *Mejelle*, which in some territories detached from the Ottoman Empire is still in force; but already the family law decreed in 1917 involved considerable encroachment upon the *Shari'a* family law, and in 1926, while Islam was still the official religion, Islamic law was entirely abolished. In Egypt family law has been revised since 1920 and the new regulations governing religious jurisdiction have transformed fundamentally the judicial procedure of the *Shari'a*; finally, Parliament has discussed profound changes in the law governing pious endowments. In Algeria and in Morocco, France has officially recognized or allowed the recognition of the Berber common law, which differs from the *Shari'a*, and has in part revised it with the intention of improving the position of women.

In conformity with its character as a religious ethic the *Shari'a* applies in general to Moslems only; the adherents of other tolerated religions, chiefly Jews and Christians, who were considered citizens of a lower class (*dhimmi*), retain in addition to autonomous administration of their cultural and religious affairs their own internal jurisdiction with recourse to the *cadi*, who decides according to Islamic law. This logical conclusion of the Islamic concept of the state has persisted in Mohammedan countries to the present time for those matters which are still regulated by the *Shari'a*. In the Ottoman Empire a community of those professing another faith within the Islamic state was called a *millet*. With the extermination of some non-Mohammedan minorities and the progressive assimilation of others to their Moslem neighbors the *millet* system has been slowly disappearing. In addition to the *millet* system there were the so-called Capitulations, which guaranteed subjects of foreign, non-Moslem states the enjoyment of their own consular jurisdiction. The Capitulations fitted without difficulty into the *Shari'a* doctrine of the protection of foreigners and were from the Islamic point of view a mere extension of the concept of the personal nature of law which held for the *dhimmi*. This like the *millet*

is disappearing or has already disappeared from Islamic territory.

G., *Handbuch der Islam-Literatur* (Berlin 1923) sect. iv, ch. v, chiefly for western publications, as well as in Aghniides, N. P., *Muhammedan Theories of Finance*, Columbia University, Studies in History, Economics, and Public Law, no. 166 (New York 1916), for the oriental sources.

ISMAIL KEMAL BEY (1844-1918), Albanian statesman. A member of the feudal family of Vlora, which owned large estates in southern Albania, Ismail belonged by descent and education to the Turcophile ruling class. After his more or less voluntary flight from Turkey in 1900, however, he joined the Albanian nationalist movement. He first cooperated with Faik Konitza in the publication of his paper, *Albania*, in Brussels, then edited his own paper, *Salut de l'Albanie*, and later became the leader of the Liberal opposition in the Turkish parliament. He is important historically chiefly for his proclamation of Albanian independence on November 28, 1912. He recognized the necessity of this step in the spring of 1912, a half year before the outbreak of the First Balkan War, in order to prevent the otherwise inevitable partition of the country. He prepared the proclamation through negotiations with the leaders of the great Albanian colony in Bucharest and with the support of Austria-Hungary and finally seized the right moment for its promulgation after the outbreak of war.

Ismail directed the government of Albania until January 22, 1914, when he surrendered his full powers to the International Commission of Control. His rule was marked by fundamental reforms, especially in the religious field. He was also active in endeavoring to preserve the territorial integrity of Albania by means of personal negotiations at Rome, Vienna, Paris and especially at the London Balkan Conference. His career as a statesman was finally terminated when after the accession of Prince Wilhelm of Wied he demanded the division of the country into three cantons after the Swiss model, the creation of Italian and Austro-Hungarian spheres of influence and the departure of the prince. The storm of opposition to these proposals forced him to flee to Italy, where he remained until his death. Although Ismail has been frequently accused of betraying his country for money, this charge has been proved to be entirely without foundation.

NORBERT JOKL

Consult: The Memoirs of Ismail Kemal Bey, ed. by Sommerville Story (London 1920); Swire, J., *Albania* (London 1929).

ISMAY, THOMAS HENRY (1837-1899), British shipowner. Ismay was the son of a shipbuilder and was apprenticed to Imrie and Tomlinson, a Liverpool shipping firm, at the age of sixteen. After traveling to South America he

became in 1860 junior partner in Nelson and Company. In 1867 he purchased the flag of the White Star Line, an Australian sailing fleet, and built iron clippers. In 1869 he founded the Oceanic Steam Navigation Company (White Star Line), running between England and the United States, which developed one of the world's leading merchant fleets. Together with the shipbuilding firm of Harland and Wolff of Belfast, Ismay produced a faster and more comfortable type of Atlantic liner than hitherto known, beginning with the *Oceanic* in 1871. Although Ismay refused to enter Parliament he was a staunch Liberal, was interested in public affairs and served on important government commissions relating to military and naval administrative questions. During the crisis of the Russo-Turkish War in 1878 he put the White Star fleet at the disposal of the government for war purposes. This tender led to the practise of state subsidy for the building of large, swift steamships transformable into auxiliary fighting cruisers or transports, and in 1897 the White Star *Teutonic* participated in a naval review as a small cruiser. Ismay contributed \$100,000 to the establishment of a sailors' pension fund. He left an estate worth more than \$5,000,000.

ISOLATION. The stability or instability of isolation depends upon the characteristics of the existing culture which forms the basis for individual and social behavior. The isolation of castes and ranks in early historical ages, for example, was relatively stable; that of social classes in later individualistic forms of civilization has been relatively unstable. A group may seek and emphasize isolation by aristocratic exclusiveness, while external egalitarian countertendencies of democracy may endeavor to abolish the isolation. Conversely, an expelled group with pariah status may try to avoid the isolation which has been imposed upon it. A voluntary isolation, which is also emotionally conditioned by hostile sentiments, has a powerful integrating effect; it turns the isolated group into a closed community and makes it tenacious and enduring. An involuntary isolation based on feelings of strangeness and indifference exerts only an associative effect and results merely in a loose and temporary external community of interests. Even under conditions of spatial symbiosis extensive isolation may exist when the demarcation of the group from its surroundings is due to psychological barriers. On the other hand, spatial

separations may be overcome by sociological and psychological bonds that transcend them. Natural topographic features, artificial national and administrative boundaries, military fortifications and prison walls furnish frames for spatial isolation. The attitude of the isolated group toward the isolation thus achieved determines whether and to what extent the available means of communication may be utilized to break down the boundaries. In some cases occasional visits of tourists to isolated communities may inspire the natives with a desire to emigrate by making them conscious of their isolation. A group of prisoners of war thrown together in involuntary isolation may be integrated by a spirit of camaraderie as a result of joint plans for escape.

The sociological composition and structure of the isolated group determines its degree of self-sufficiency and power of survival as well as its capacity for adaptation to changed temporal and cultural conditions. The self-sufficiency of an isolated group may increase—either in respect to its needs, as, for example, by the habituation of the group to primitive conditions or to solitude, or in respect to the satisfaction of its needs through a change in the economic situation or in the conditions of communication. The character of the biological results of isolation, such as inbreeding, susceptibility to certain diseases and the effect on birth and death rates, as well as the nature of the effects of tradition and habit, such as peculiar customs and handicrafts, is also dependent upon the composition and structure of the isolated group. Social, religious and ethnic uniformity or multiplicity, the possibility of changing one's mode of life within the isolated group, the normal or abnormal ratio of the sexes or of different ages, the variability of the size of the group and the possibility of territorial extension are among the decisive factors involved. Both the absolute size of the group and its numerical ratio to its immediate environment are also important in determining the specific effects of isolation.

The sociological basis of isolation may change: religious isolation may turn into national or national into economic. Often the basic legal reason for isolation is eliminated as a result of historical changes, but the isolation may continue either because of political or economic privileges or because of mere habit. Involuntary isolation may change into voluntary isolation and vice versa, or an isolation originally spatial may become independent of such barriers. Barracks,

boarding schools, college dormitories and sanatoria are examples of forms of temporary isolation which are widely used as community measures to increase individual and collective efficiency. Religious struggles and nationalist movements may result in the isolation, by mass emigration or demarcation, of certain groups, which may become integrated in ethnic communities. Only after the original cause of the isolation is no longer effective can it be determined whether and under what conditions the isolation will be maintained and whether a return to and merging with the old condition of life or a separation and dissolution into a new will follow. The abolition of the ghetto, for example, has had national, cultural and religious assimilatory effects; it has also resulted in the formation of special religious and political groups, such as that of the Zionists.

Isolation may be on one side only, as when a group is expelled from a society and is avoided or when the group isolates itself; in both cases it lies in the discretion of the society to maintain the isolation or at least to make an endeavor to break through it. Component states of a federative empire and church parishes, on the other hand, are examples of mutual forms of isolation. Most forms of specific isolation presuppose complementary behavior in other respects. A troop of prisoners of war isolated by military authority requires measures of supervision and feeding which in part annul the isolation. An aristocracy which isolates itself permanently requires an extensive servant class, which it trains in order to be able to separate itself from the mass of the people. Thus any kind of isolationist action is accompanied by associatory auxiliary activity directed toward attaining the ends of isolation; often these auxiliary factors contain the germs of the forces which are destined to burst the bonds of the isolation.

Problems arising from isolation are to a certain extent related to differentiation and individualization on the one hand and to integration and leveling on the other. Cultures in which agriculture predominates are characterized by isolation; while nomadic, hunting and military cultures counteract isolation by communication and mobility. Mutual isolation aids the continuity of cultural forms but also results in the gradual differentiation of originally homogeneous social elements because of differences in the tempo of development; for example, in the field of language where ancient and undeveloped forms of speech and dialects persist. Isolation

tends to dissolve and hinder the development of large units, societies and groups; but it may be to the advantage of a people to maintain reserve forces which are removed from the cultural effects of urbanization through the isolation of its rural population or the inhabitants of its remote districts. This may have a negative, narrowing, stunting and one-sided effect upon the isolated group but it may also exert a positive effect through intensifying characteristic features of its culture. Social institutions which serve to isolate certain subgroups may in this way lead to the accumulation of outstanding achievements of a political, scientific or technical nature in these subgroups through specialized tradition which benefits the entire culture.

The spread of world religions; the rapid advance of techniques of communication; the opening of remote and sparsely settled regions; movements involving democratization, urbanization and industrialization; the present interrelations of world economy; the formation of huge empires; and the mobilization of the earth's population in the World War, have resulted in the pronounced decline of the tendency toward voluntary isolation. The isolation which still exists is in a very unstable condition. The trend away from the land, the movement of populations from high mountain zones, are phenomena which favor association and intermixture rather than isolation. On the other hand, during the present world economic crisis there is a revival of the phenomena of isolation resulting from protective tariff policies, trends toward economic self-sufficiency and the development of nationalism of small countries. Likewise there is in many places a countertendency against cosmopolitanism and against the obliteration of denominational, social and national peculiarities which is using isolation as a method rather than as a permanent form.

ISOLATION, DIPLOMATIC. Diplomatic isolation involves the enforced exclusion or the voluntary and deliberate abstention of a state from the councils of the powers or from participation in affairs of general interest. From the sixteenth to the nineteenth century international affairs centered largely upon the relations of the great powers of Europe to one another. The guiding principle was balance of power, a principle which involved action to prevent the concentration of undue influence and power in any one state. It was therefore a common practise for powers which felt themselves threatened by the predominance of another to unite against the latter, to isolate it if possible and eventually to break its preponderance by military defeat. Such was the nature of the alignment and conflict against the Hapsburg power in the sixteenth and seventeenth centuries, against the power of France in the periods of Louis xiv and Napoleon and against the new Prussian state of Frederick the Great in the Seven Years' War. At this period the isolation of the power to be attacked was part of the regular preparation for war and part of the accepted strategy of diplomacy. The coalition which preceded the War of the Spanish Succession, the famous Diplomatic Revolution of 1756, the combination of powers which dismembered Poland and the alliances against France in the revolutionary and Napoleonic periods are all classic examples of international groupings designed to isolate the power against which the action is directed.

But the isolation of a power was not necessarily a preliminary to armed conflict. It might be effected for prophylactic purposes with the idea of preventing such conflict or aggression. It then frequently involved the union of power and influence of a number of smaller or weaker states against one large or powerful state. Examples of this practise may be found in the *Fürstenbund* organized by Frederick the Great against Joseph

II of Austria and in the so-called Armed Neutralities of the later eighteenth century.

The growth of the idea of the concert of Europe and the spread of the idea of cooperation among nations made the application of the policy of isolation less frequent in the nineteenth century than in the days of the old cabinet diplomacy. In the years following the Napoleonic wars France was very effectively isolated by the Quadruple Alliance, and the victorious powers attempted to prevent the recrudescence of aggressive policy by building up a bulwark of powers on the French frontiers as well as by means of an allied occupation of French territory and the imposition of a heavy indemnity. But France was readmitted to the councils of the powers at the earliest possible moment. She was effectively isolated again, in the purely diplomatic sense, in 1840, when four great powers united to impose a solution of the eastern crisis from which France dissented. In the years preceding 1870 Napoleon III attempted to isolate Prussia by effecting a combination between France, Austria and Italy, but this policy was frustrated by Bismarck when he forced the issue in 1870 and completely defeated France. The roles were then reversed, and in the period from 1870 to 1890 the German chancellor devoted his efforts to the construction of a great alliance system which was designed to prevent France from finding among other powers support for her aspirations and hopes for revenge. The Franco-Russian Alliance of 1894 put an end to France's isolation, and with the building up of the Triple Entente in the years 1904 to 1907 it was the Germans who began to fear isolation and talk of "encirclement." In reality no European power was isolated in the period immediately preceding the World War. It was not until after the defeat of the Central Powers that the old policy was put into practise once more. The French system of alliances with states like Poland, Czechoslovakia, Yugoslavia, as well as the combination of states known as the Little Entente is designed to isolate Germany and Hungary and to provide protection for all eventualities. Similar efforts were made in the post-war period to isolate Russia and to cut her off from intercourse with the other powers.

These examples will show that isolation may be carried out for aggressive or defensive purposes, in modern times more commonly for the latter than for the former. It may be effected by various methods. Usually the effort is made to construct a coalition of powers which will ef-

fectively deprive the state acted against of support from outside, according to the principle enunciated by Bismarck that in a world of five great powers a state should always strive to be one of the group of three. Powers centrally located are always more exposed to isolation than those on the fringe, so to speak. A central power may be surrounded by a group of hostile states and completely hedged in by enemies. It is also more exposed to economic and financial pressure, to curtailment of food supply and to other restrictive measures made possible by the improved methods of communication and transportation. But isolation in the broadest sense of the term can rarely if ever be successful. Politically speaking the friendship of a state threatened by isolation can usually be had so cheaply that it will inevitably find a bidder and the coalition opposed to it will soon begin to disintegrate. On the other hand, the modern world is economically so much of a unit that states have become interdependent in politics as well. For that reason complete isolation is impossible and the policy of isolation has become a dangerous anomaly. In the future it is bound to become more and more a purely punitive measure directed against an offending state by the decision of a supernational tribunal.

Of very different nature is the deliberate abstention of a state from the councils or actions of the powers. Small or weak states even on the continent of Europe have frequently followed a policy of self-imposed abstention in all disputes of a military or political nature. In the case of Switzerland this end has been attained by the acceptance of neutrality, internationally recognized. In the case of states like the Netherlands and the Scandinavian group it goes no further than refusal to become involved in territorial disputes or military operations. None of these states have ever shown the least disinclination to cooperate with other states in work of common interest, especially in work in the interest of peace. On the contrary, they have generally taken an exceptionally active part in all movements for international cooperation.

States geographically separated from Europe have generally tended to stand somewhat aloof from continental squabbles. Far from dreading isolation they have extolled it and urged it as a national policy. Thus the English since the time of Wolsey have been ardent advocates of the principle of balance of power on the continent, but they have usually tried to abstain from interference with continental affairs except when the

equilibrium was threatened or when direct English interests—political in the case of Hanover, but usually commercial—were involved. During the nineteenth century the representatives of the Manchester school carried the doctrine of abstention to extremes, making a veritable dogma of "splendid isolation." In the time of Gladstone and Granville there was little interest in the political affairs of the continent and England's prestige sank rather low. But this was merely a passing phase. Even the most irreconcilable Manchesterites never advocated abstention from anything but political and military affairs. They favored closest commercial intercourse and were convinced workers in the cause of peace and international understanding. The Conservative party and later the liberal-imperialist group always took an active interest even in political matters of international concern. Lord Salisbury while he abstained from definite written commitments aligned his country with the continental groups and his successor brought the period of isolation to an end with the signature of the Anglo-Japanese Alliance. A Liberal ministry approved the entente with France and concluded the agreement with Russia. Both parties approved of England's intervention in the World War, and in the post-war period England has played a prominent and important part in international affairs. Manchester doctrines are now forgotten and both the imperialist and labor movements presuppose active participation in world affairs.

Perhaps the most remarkable example of deliberate abstention in international politics is to be found in the foreign policy pursued by the United States government for over a century and still regarded by many Americans as a sacred legacy. The fathers of the country, mindful of the days when the colonies were still mere pawns in the game of European diplomacy, were at one in their aversion from entanglement with the European system. Their feelings in this matter were undoubtedly accentuated by their fear for the young republic, regarded with hostility by the European monarchies. "We ought to lay it down as a first principle and a maxim never to be forgotten, to maintain an entire neutrality in all future European wars," said John Adams in 1775. Jefferson thought that the new nation should "stand with respect to Europe precisely on the footing of China" and should, like the Turks, keep out of European affairs. Congress in 1783 resolved that "the true interest of the states requires that they should be as little

as possible entangled in the politics and controversies of European nations," while Washington in his Farewell Address gave classic expression to the idea in these words: "Europe has a set of primary interests which to us have none or a very remote relation. Hence she must be engaged in frequent controversies, the causes of which are essentially foreign to our concerns. Hence, therefore, it must be unwise in us to implicate ourselves by artificial ties in the ordinary vicissitudes of her politics or the ordinary combinations and collisions of her friendships and enmities."

It should be noted that Washington himself declared that "we may safely trust to temporary alliances for extraordinary emergencies" and that his objection was chiefly to "permanent" alliances. Jefferson too, who used the famous phrase "entangling alliances" in his inaugural of 1801, had no objection to cooperation for specific purposes, as in the case of the Monroe Doctrine negotiations of 1823. Nevertheless, throughout the nineteenth century American statesmen were prone to place a strict interpretation upon Washington's words and frequently refused cooperation with European powers even in cases where these interests were identical with American interests. Often in such cases the American government took exactly the same action while refusing joint action. On the other hand, there were notable exceptions to this general rule. At the time of the Hungarian Revolution of 1848-49 the United States assumed a stand not far removed from interference in the domestic affairs of another nation. At other times the government expressed itself very strongly in behalf of the Irish and of the Jews in Russia and Rumania. In Latin American affairs the abstention practised toward European questions was never observed. As early as 1826 Congress voted to participate in the Pan-American Congress at Panama and in 1875 Secretary Fish went so far as to propose to European powers that they intervene jointly with the United States to restore peace between Spain and the Cuban rebels. Much the same attitude was taken toward far eastern issues. In 1864 the United States acted jointly with Great Britain, France and the Netherlands against Japan. It cooperated with the other powers at the time of the Boxer rebellion and took the initiative in putting forward the doctrine of the open door. President Roosevelt took a lively interest in the Russian-Japanese conflict and acted as intermediary to bring about the conclusion of peace. In general then it may be said that American isolation was maintained chiefly with regard to

the political alignments and affairs of Europe. As international cooperation developed in the later nineteenth century the government took part in many conferences for the regulation of the postal services, weights and measures, cables, copyrights, sanitary services, sea law and other matters. The United States took an active part also in the work of the two Hague peace conferences, to say nothing of the essentially political conferences on the affairs of Morocco (1880), the Congo (1884-85) and Morocco again (1906). The action of the government in the last named instances roused much opposition, but there was in the pre-war period a growing feeling, eloquently expressed by men like Senator Lodge, that Washington's words must not be too strictly construed and that the United States with growing commerce and interests abroad could not and should not stand aloof from matters of general concern. In the World War the principle of isolation was completely discarded and the United States became deeply involved even in the affairs of Europe. President Wilson was an opponent of the ideas of the balance of power and the "game" of the old diplomacy, but he was a vigorous advocate of international cooperation for the advancement of peace, security and the common interests of mankind and insisted that "there is no entangling alliance in a concert of power." His policy, which is best set forth in the Covenant of the League of Nations, met with bitter opposition from the leaders of the Republican party, notably from Senator Lodge, who evidently changed his attitude to meet the exigencies of party politics. The peace treaty with Germany, the Guarantee Treaty with France and the Covenant of the League were rejected by the American Senate, although the same body raised little objection in 1922 to the so-called Four-Power Treaty relating to the Far East. The conflict which arose over the action of President Wilson did, however, lead to a revival of the isolationist teaching, and the experience of 1920 has made the government wary of far reaching commitments. But the growth of American commerce, the increasing export of capital, the ramifications of the reparations and interallied debt problems, have involved the United States so deeply in general world affairs that the government has been obliged to take an active part and even to collaborate with the League, unofficial though its action at times has been.

In the modern world with the growing economic and therefore political interdependence of nations it is quite as impossible for a state to

maintain a deliberate isolation as for a group of states to impose isolation on any other. The machinery of the League of Nations is designed to prevent a recrudescence of the old diplomacy and to replace purely selfish, national action by international cooperation. The old system and the old practise continue, but they are falling into ever greater disrepute and are bound gradually to disappear as the new system establishes itself.

ITAGAKI, COUNT TAISUKE (1837-1919), Japanese politician and statesman. From early youth Itagaki identified himself with the contemporary movement for the restoration of the authority of the emperor and represented his native clan of Tosa, one of the four influential daimios allied against the then tottering Tokugawa shogunate, in Kyoto, the center of the anti-shogunate forces. When the new Japan was being organized under imperial control, he headed an expeditionary force sent to bring about the submission of the feudatories in the north who were supporting the shogun against the emperor.

Itagaki was one of the builders of modern Japan. He was the minister of industry in the new imperial government but resigned from office when the ministry refused to declare war on Korea. Seeing in this a defeat of popular sentiment he started the agitation for a parliamentary form of government in Japan. To further his program he established an educational institute (Risshi-sha) in which the students were taught the principles of parliamentary govern-

ment and which served as a model for similar schools. In 1881 he succeeded in organizing under his leadership the first nation wide political party, which was known as *Jiyuto*, or Liberal party. In 1887 in recognition of his distinctive services to the country he was created a count, an honor which he vainly tried to decline because of his opposition as a Liberal to the institution of a hereditary peerage. Later, when the constitution was proclaimed and the parliament established, he was twice recalled to the government's service as minister of the interior. His political importance ceased, however, in 1900 when his party was merged into the *Seiyukai*, a new party under the leadership of Prince Ito. The rest of his life was devoted to the cause of social reform.

RYUSAKU TSUNODA

Consult: Morris, J., *Makers of Japan* (London 1906) ch. xviii; Uyehara, G. E., *The Political Development of Japan 1867-1909* (New York 1910) p. 89-91.

ITO, PRINCE HIROBUMI (1841-1909), Japanese statesman and diplomat. The son of a samurai in the fief of Choshu under Lord Mori, Ito was trained in the Chinese classics and military science but after Commodore Perry's arrival in Yeddo Bay he turned his attention to the study of English. Disregarding the law which forbade all Japanese to go abroad, in 1863 he secretly went to England, where he studied the language and was impressed by the material achievements of western civilization. The next year he returned to Japan hoping to dissuade Lord Mori, who had been bitterly opposed to the shogunate's policy of opening the country to international intercourse, from bombarding foreign vessels passing through the Strait of Shimonoseki and subsequently negotiated an agreement between the warring parties. From then on he was almost continuously in the government service and held many important posts, including those of vice minister of finance, minister of public works, minister of home affairs and prime minister.

Ito was one of the leaders in developing modern Japan and was intimately connected with many reforms, including financial reorganization. In 1870 he went to the United States to study its monetary system; and in 1871 the government upon his recommendation adopted the gold standard, which was later changed to a bimetallic system. But in domestic affairs he is known especially as the father of the constitution. Between 1882 and 1883 he traveled abroad studying the constitutions of European nations and

upon his return drafted the constitution which was promulgated in 1889. Believing that Japan was not ready for truly representative government and anxious to preserve the traditional political principles of the Japanese, Ito embodied in the constitution the complete authority of the emperor in conjunction with decidedly limited representative institutions. From 1890 on he helped to steer the government on its difficult course, constantly hampered as it was by the immature party politics which marked the history of early constitutional Japan. He himself remained aloof from political parties until in 1900 he became president of the *Seiyukai* party and organized his fourth and last cabinet.

In foreign affairs also he was a dominant figure. He visited the United States and Europe from 1871 to 1873 as a member of the famous Iwakura mission, the object of which was to secure treaty revision and to gather information on administrative matters. In 1895 as prime minister he signed with Li Hung Chang the Shimonoseki Treaty, which ended the war with China but which brought about Russo-German-French intervention compelling Japan to retrocede the Liaotung Peninsula to China. In 1901 he went to Europe with the idea of entering into an entente with Russia on the Manchurian question, but the Katsura cabinet rejected his recommendations and entered instead into an alliance with England. He favored an understanding between Russia and Japan, because he believed that it would lead to a peaceful settlement of their conflicting interests whereas the British alliance would only tend to aggravate the situation. From 1905 to 1909 he was resident general of Korea and inaugurated a program of widespread reform, which, however, he was unable to realize completely. He was assassinated by a Korean in 1909.

KIYOSHI K. KAWAKAMI

Consult: Lawton, Lancelot, "Prince Ito: His Life Work and His Influence upon the National Policy of Japan" in *Imperial and Asiatic Quarterly Review*, 3rd ser., vol. xxix (1910) 308-37; Morris, J., *Makers of Japan* (London 1906) ch. vi; Treat, P. J., *The Far East* (New York 1928); *Kaikoku Gojūnen Shi*, compiled by Count Shigenobu Ōkuma, 2 vols. (Tokyo 1908), tr. as *Fifty Years of New Japan*, ed. by M. B. Huish (London 1909).

IVAN IV (Ivan the Terrible) (1530-84), czar of Russia. Ivan was orphaned as a child and the great Muscovite boyars ruled in his name with such disregard for his person as to arouse him to passionate hatred of the old aristocracy and strong desire for autocratic rule. His personal

reign began in 1547, when he adopted the title of czar. For a few years his rule was peaceful: he issued a law code, established elective local government, initiated national consultative assemblies with local representation (*zemskie sobori*). In 1560 he broke definitely with his former advisers and surrounded himself with people of non-aristocratic origin. This marked the beginning of a new era, which culminated in 1565 in the creation of a personal bodyguard (*oprichniki*); it was to protect the czar, who suffered from a delusion of persecution, scented treason everywhere and acted with pathological cruelty. The *oprichniki* carried out a policy of ruthless terrorism directed at first against the princes and boyars and later against other classes as well. The power of the landed aristocracy was undermined by the expropriation of its patrimonial estates, and the class of small and middle landed gentry (*dvoryane*) was thereby raised in importance. As vassals of the state the latter were obliged to perform military service for life, and their estates were inalienable, uninheritable and recapturable by the state for abuse of official duties. At the same time the peasants gradually lost the right of changing their masters; this process of binding the peasant to the soil was not completed, however, until the early part of the seventeenth century. Russia was thus transformed from an aristocratic state into an oppressive autocracy with the population bound to a variety of compulsory services and suffering from the excesses of official terrorism.

Ivan's reign was marked by great territorial expansion of Russia. As a result of the conquest of the Tartar khanates of Kazan in 1552 and of Astrakhan in 1556 areas along the entire course of the Volga were annexed. In 1582 western Siberia was added. In 1558 Ivan opened war on Livonia for control of the Baltic coast, later extending it against Sweden and Poland; the war continued with varying fortunes until 1582, when domestic disorder caused its collapse.

IXTLILXÓCHITL, FERNANDO DE ALVA (c. 1578-1648), Mexican historian. Ixtlilxóchitl, a mestizo, was the direct descendant of the poet and sage, King Netzahualcōyotl of Tezcuco, and of the Aztec king Cuitlahuac, who drove the Spaniards out of the city of Mexico in June, 1520, in the famous *noche triste*. He possessed an intelligent and profound knowledge of the historical tradition, language and hieroglyphic writing of his indigenous ancestors and devoted a great part of his life to the writing of numerous works concerning the historical evolution of New Spain from the remotest times to the seventeenth century. These works show Christian and Spanish influences, but as they seek to glorify the culture and exploits of his Tezcuco ancestors they represent in certain respects the native point of view. Ixtlilxóchitl considered the history of his people to be as important as the histories of the Romans or the Greeks. On the other hand, the nineteenth century Mexican patriots who, seeking to exalt their country's Indian traditions, circulated a portion of his work as a faithful and candid description of the "horrible cruelties of the conquerors of Mexico and of the Indians who aided them" were uncritical in their methods and unmindful of obvious differences between their attitude and his. The widely diffused but disputed impression that the Spaniards barbarously obliterated the carefully kept records of a remarkably high civilization in Mexico rests to a considerable degree on his statements. He explained the advanced character of this civilization by the influence of an idyllic Toltec people whose very existence was long denied. His credulity—modified, however, by euhemerism—his partisanship and the use of his work for partisan purposes have served to discredit Ixtlilxóchitl. Nevertheless, his writings, which constitute a rich source of data on Mexican ethnography, hieroglyphics, linguistics, folklore and poetry, are of value to the investigator who seeks to understand the social phenomena that characterized the pre-Hispanic life and the first contacts of Spaniards and aborigines.

MANUEL GAMIO

Works: *Obras históricas*, ed. by A. Chavero, 2 vols. (Mexico 1891-92). The majority of Ixtlilxóchitl's works are to be found in Kingsborough, E. K., *Antiquities of Mexico*, vol. ix (London 1848) p. 197-467.

IZVOLSKY, ALEXANDER PETROVICH (1856-1919), Russian statesman and diplomatist. Izvolsky, a member of the lesser rural nobility, entered the Foreign Office under Prince Gorchakov and was appointed successively to diplomatic posts at Bucharest, Washington, the Vatican, Belgrade, Munich, Tokyo and Copenhagen. Long before the revolutionary outbreak of 1905 he foresaw the dangers that beset Russia from the short sighted bureaucracy which surrounded Nicholas II. Sympathizing with English liberalism, he desired the gradual introduction of a parliamentary system.

As minister at Tokyo Izvolsky had the wisdom and insight to warn his government that a continuation of the Russian policy in Manchuria would lead to war with Japan. His warning was unheeded, but its verification enhanced his reputation and after a short residence at Copenhagen he was appointed Russian minister of foreign affairs. Ambitious to regain for his country the prestige lost in the Far East, he undertook to advance Russian interests in the Near East. As a first step he negotiated the Anglo-Russian Convention of 1907, smoothing out rivalry in Tibet, Afghanistan and Persia and establishing with France the Triple Entente. Then he secretly proposed to Count Aehrenthal at Buchlau that Austria should annex Bosnia and Herzegovina and that in return the straits of Bosphorus and Dardanelles should be opened to Russian warships. Aehrenthal quickly secured his part of the bargain, but England opposed Izvolsky's proposal for opening the straits. This diplomatic failure caused him to be severely criticized in Russia and greatly embittered him for the rest of his life against Austria. It was one of the reasons for his giving up the Foreign Office in 1910 to go as Russian ambassador to Paris, where he served until the establishment of the Kerensky government in 1917. At Paris he cooperated with French officials, especially with Poincaré, in strengthening and tightening the Triple Entente in preparation for a war which should at last secure Russia's ambitions in the Near East.

Consult: The most exhaustive collections of Izvolsky's

diplomatic correspondence are *Der diplomatische Schriftwechsel Iswolskis*, 4 vols. (Berlin 1924), covering the period from 1911 to 1914, and *Iswolski im Weltkrieg . . . 1914-17* (Berlin 1925), both edited by Friedrich Stieve and drawn from earlier collections based on Russian archive material. A historical analysis of the documents may be found in Stieve, F., *Iswolski und der Weltkrieg* (Berlin 1924, tr. by E. W. Dicks (London 1926). Izvolsky's earlier career is sketched in his *Memoirs* (Paris 1923), tr. from ms. by C. L. Seeger (London 1920). For the general diplomatic background see Fay, S. B., *Origins of the World War*, 2 vols. (2nd rev. ed. New York 1930).

JABAVU, JOHN TENGO (1859-1921), Bantu politician and publicist. Jabavu was the most prominent of a small group of educated Bantu who interpreted the needs of their race while it was first being brought under the influence of the culture and political institutions of South Africa's white rulers. For nearly forty years he owned and edited the English-Xosa weekly newspaper *Imvo zabantsundo* (Native opinion) and took a leading part in Bantu religious, educational and political movements. His efforts resulted in the grant of free primary education and the establishment of the South African Native College, which provides university training. Moved by a liberal attitude founded on religious convictions which became more and more influenced by Quaker thought, Jabavu believed in democratic government, for the introduction of which he considered the Bantu tradition of free public discussion a sound background. On several occasions he protected with courage and ability the Cape franchise, free from the color bar. He led his people in resisting many repressive educational and land tenure measures and fought against harsh treatment of rebellious chiefs who had lost their independence. He declined to run for the Cape house of assembly on the ground that the presence of a native would be premature and more dramatic than politically effective; instead he urged the support of a liberal white candidate. Toward the end of his life his popularity waned on account of party differences over the Native Land Act of 1913 and on account of opposition to his leadership by the Xosa section of the Cape because he was a Fingua and thus considered outcaste. Under Jabavu's leadership the Bantu peoples raised themselves in the estimation of the white men in South Africa.

JACINI, STEFANO FRANCESCO (1826-91), Italian economist and statesman. Jacini's father owned and administered vast estates and silk factories, and Jacini himself became early interested in agricultural problems. The events of 1848-49 interrupted his study of law, but he did not, like the majority of Lombard youth, volunteer in the Italian army; study in Switzerland and Austria and extensive travel turned him toward cosmopolitanism and he displayed an innate aversion to revolutionary methods. A few years later, however, he rendered conspicuous service to the Italian cause by his writings, which although cautiously phrased to avoid police action demonstrated incontrovertibly that the unfortunate condition of Lombardy was due to Austrian misgovernment. Jacini's works were immediately received with high praise in Italy and abroad; Cavour after secret communications with him chose him as one of his ministers almost immediately after the liberation of Lombardy in 1860. He served until 1862 and again from 1864 to 1867. He was prominent in reorganizing and unifying the railroads and other public services and was most influential in forwarding the construction of the St. Gotthard Railway connecting Italy with Germany. Later he sat in the Senate and directed the parliamentary commission for agricultural inquiry (1877-85). For the report of this commission he prepared the introduction, the section on Lombardy and the final summary; the last served as a model for many similar studies and was regarded as the most authoritative presentation of agrarian conditions in pre-war Italy.

JACKSON, ANDREW (1767-1845), seventh president of the United States. Jackson had served short terms in Congress as representative and senator from Tennessee (1797-98) and six years as a justice of the state Supreme Court (1798-1804) when his defeat of the British at the battle of New Orleans on January 8, 1815, made

him a national hero. He added to his fame by his invasion of Florida in 1818 at the outbreak of the Seminole Indian War and by his high handed treatment of the Spanish authorities there. From 1823 to 1825 he was again a senator from Tennessee. His personal popularity and violent and contentious temper rather than his championship of any clearly defined political principles made him the most conspicuous embodiment of the spirit of discontent which came to a head after the panic of 1819 and of a rising demand in the west for general political and governmental reform. His presidential candidacy was aided by dissensions in the cabinet of President Monroe and by a popular demand for the abolition of the congressional caucus, which in the absence of a national convention system had assumed to make nominations. In 1824 he received a plurality of the electoral votes but was defeated in the House of Representatives by John Quincy Adams, who received the votes of the supporters of Henry Clay. Jackson accepted the result as constitutional but spread the charge of a corrupt bargain on the part of Clay and was acclaimed as the predestined candidate of the Democrats in 1828. In that year he was triumphantly elected and at once instituted a partisan purge of the federal civil service and pressed a demand for economy, which included by 1835 the virtual extinction of the national debt. The other outstanding episodes of his two administrations (1829-37) were his vigorous resistance to nullification in South Carolina; his attack upon the second Bank of the United States, whose recharter he prevented; his refusal to support the Supreme Court in its adjudication of the rights of the Cherokee Indians; and an order directing specie payments for public lands which contributed directly to the panic of 1837. A resolution by the Senate censuring him for his course with the bank and its deposits was met by protest which arraigned the Senate and stoutly defended his executive prerogative. In his insistence upon "the people" as the source of political power and his espousal of the theory of majority rule his conception of democracy accorded with that of Jefferson, but the people to him meant the masses and the importance which Jefferson attached to the agricultural class as the foundation of a democratic society had no special place in his thought. With none of the cultural background or intellectual interest of Jefferson, he interpreted public opinion by his intuitions and desires, regarded his own understanding of the constitution as of equal authority with that of

the courts and as an executive showed himself an autocrat. The antimonopoly feeling of the time had his sympathy, but his financial policy showed little understanding of either banking or credit functions or the needs of an expanding industrial and commercial order. His hold on the popular imagination of his own and later generations may be attributed to his ruthless vigor as military leader and champion of the people, to his devotion to the union in opposition to the disintegrating influence of the doctrine of state rights and to his combination of high political principles with a realistic playing of the political game.

JACOBINISM. This word may be used to describe a specific phenomenon of the French Revolution or to describe a widespread but rather loose and indefinite form of corporate faith and organization which indeed took its start from revolutionary France but which pervaded the whole western world for several generations. Jacobinism in this sense had for perhaps a hundred years the same sort of meaning which Bolshevism has today; that is, it was quite indiscriminately applied by political conformists to their opponents generally, and it had definitely dyslogistic overtones. The epithet Jacobins, drawn from their meeting place in the library of a Jacobin convent, was fastened by contemporary popular usage on the Société des Amis de la Constitution of Paris, a political club originating immediately in a caucus of radical Breton delegates to the Estates General and ultimately springing from the rich group life of the last decades of the old regime—salons, local academies, literary societies and Masonic lodges. The Paris society was founded by radical deputies who wished to create organized support for themselves outside the Assembly and soon came to include journalists, municipal politicians, professional men; in fact, anyone actively interested in what was to Frenchmen the new pursuit of politics. Similar clubs soon grew up in the provinces and were affiliated with the "mother

society" at Paris in a network admirably organized all over the country. The membership of these clubs was pretty uniformly middle class and respectable throughout the revolution, and it was recruited chiefly from merchants and professional men; at most it may be said that after the founding of the republic there was a slight relative increase in the number of shopkeepers and artisans. Proletarian these clubs almost never were, even at their fieriest. The total number of Jacobin clubs in France was probably between five and eight thousand; their total membership over the whole course of the revolution may have been close to a million, but during the Terror it can hardly have been much over one half that figure.

The Jacobins began as a pressure group similar in some ways to the Anti-Corn Law League or the Anti-Saloon League. Their network of affiliated societies, centralized through the Paris society, gave them access to all France. Their use of propaganda was highly modern and efficient. Newspapers were subsidized, pamphlets circulated through the mails, prizes for *civisme* offered to school children, revolutionary almanacs distributed, theaters encouraged to provide such patriotic spectacles as the Fall of the Bastille and the Death of Caesar. Direct pressure was brought to bear on elections both local and national. Candidates were pledged to carry out Jacobin measures in return for the club's support, opponents were shouted down or even terrorized—an easy matter in the direct primary assemblies—and an excellent political machine constructed. Few men were elected to the Convention without the support of their local club.

All this pressure was brought to bear in 1792 and 1793 toward the establishment of a republican form of government, universal manhood suffrage, equality before the law, a rough economic equality to be attained by the free play of individual competition and the voluntary restraints of republican morality, universal education and separation of church and state—substantially the ideology of eighteenth century rationalism. These aims would seem to have been implicit among the Jacobins from the very start and to have been their real purpose even in 1790. Official historians of the revolution, however, like Aulard and Mathiez, have considered the anticlerical republican program of the Jacobins a product of conservative stupidity and the European war. Many of the early Jacobins were indeed Girondins in sympathy and believers in *laissez faire*, moderation and local self-

government. Pure Jacobinism was authoritarian, radical and strongly in favor of centralization. Yet there was much pure Jacobinism, especially anticlericalism, among the early clubs and by July, 1793, avowed Girondists and other moderates had been driven from the clubs.

The Jacobins, however, were more than a pressure group or a political party. They succeeded in investing their rather commonplace principles—even in the late eighteenth century they were commonplace—with the satisfying glories of religion. Quite early in the movement the club meetings took on a ritualistic touch. Club premises, at first adorned with a bust or so, Voltaire, Rousseau, Franklin, Brutus, accumulated an extraordinary number of sacred objects. Revolutionary hymns were sung and responsive readings were followed by moral sermons. The young were taught in revolutionary Sunday schools. Civic processions, civic festivals and love feasts, initiated and administered by the clubs, were perhaps too consciously worked out as ritualistic substitutes for Christianity. The details of this Jacobin ritual were a hodgepodge of misapplied Roman history, Rousseauistic sentimentalism, eighteenth century rationalism, downright borrowings from Catholic practise and even immemorial folk custom. Too crude for men of taste, too unreal for the masses, this ritual seems to have been real for the Jacobins. Their meetings displayed many phenomena which the psychologist must recognize as the phenomena of religious belief: violent intolerance of slight dogmatic differences, consciousness of being persecuted, total want of a sense of humor, a contagion of mass emotion, a conviction that opponents are not merely in error but in a state of sin. It is this religious exaltation that would seem to explain the Terror. There is nothing in the social origins or in the specific grievances of the Jacobins adequate for such an explanation. No doubt the constant fear of royalist and foreign enemies augmented the violent manifestations of this faith; but the faith itself, the force behind the "Republic of Virtue," must be traced in the complex fabric of eighteenth century thought and emotion.

The Jacobin clubs during the Terror were hardly more than places for revolutionary worship. No doubt the revolutionists spurred each other on in club meetings and maintained their spiritual energies. But from a third to a half of the members of many clubs were functionaries of the new government. Naturally enough the clubs ceased their old activities as pressure

groups. After the autumn of 1793 they no longer resisted a government of which they formed the rather narrow base. Such political discussion as there was took place in the clubs. Elections were supplanted by *épurations* at the dictate of the representative on mission, and here again the clubs stood for the people. Some minor administrative work was done by the clubs—gathering saltpeter, policing the market, maintaining the maximum on prices. After Thermidor the clubs died out fairly rapidly. They did not protest the fall of Robespierre—indeed by 1794 they accepted anything done at Paris. But they were inconvenient to the Thermidorians, since the earnest Jacobin took liberty, equality, fraternity too literally for the profiteers, the tired ordinary bourgeois and the peasants of the new regime. By 1795 the remaining clubs had been closed. Many ex-Jacobins were to enter the civil service of the emperor. From Fouché, who became Napoleon's indispensable minister of police, to Picqué, who had the relatively humble post of *chef de contentieux* in the imperial lottery, the *conventionnels* did but set the lead for hundreds of Jacobins in the provinces. Former revolutionists were as indispensable to Napoleon's civil administration as to his army.

After the first spontaneous delight with which most of the world hailed the beginnings of the French Revolution, the extraordinary radiation of that movement was largely the work of Jacobins in France and out. Jacobin clubs were immediately set up in territories conquered by republican armies—Nice, Savoy, Italy, Belgium, the Rhineland. French soldiers and civil servants mingled with a number, never very large, of natives. In England societies like the London Revolution Society were already in existence, although somnolent. The French Revolution gave a great impetus to groups working for a reform of Parliament and led to the formation of Hardy's London Corresponding Society, a club largely recruited from artisans, to the Society of Friends of the People—a highly Gallic name—and to many other such societies in London, in the provinces and in Scotland. There was a certain amount of centralization and common deliberation but nothing like the Jacobin network in France. In the United States, democratic, sometimes republican or constitutional, societies sprang up in pretty close imitation of the French and a system of affiliation and correspondence was worked out.

There was unquestionably a certain amount of mutual intercourse between French Jacobins

and their sympathizers in Europe and America. International Jacobinism was never a conspiracy, although to many a conservative it seemed one; and Frenchmen did not swarm secretly into foreign countries supplied with armfuls of gold to build up political clubs, although that too was charged against them. But travel was relatively easy, and Jacobinism aspired to be a world religion. Foreigners like Cloutz, Paine, Pigott and Georg Forster played various roles in French revolutionary politics. Frenchmen descended in numbers into Nice, Savoy and the Rhineland. Margarot, who figures prominently in the English and Scottish clubs, was a Frenchman. The club of Charleston, South Carolina, which actually got itself affiliated with that of Paris, contains many French names, not all of which seem to be those of Carolina Huguenot families. The role of republican ambassadors, Genêt in America, Chauvelin in England, Bassville at Rome, is of course familiar. Correspondence was even more frequent than personal contact. The Paris society corresponded with several English societies until the war and sent a good deal of literature abroad. Finally, French political debates were abundantly reported both in English and in American newspapers and periodicals.

The similarities between French clubs and clubs outside France were striking. The phraseology of the addresses issued by American clubs, their abstract and grandiloquent prospectuses and preambles, sound as though they were translated from the French, which in part they undoubtedly were. In Germany and Italy the same was true, although there the clubs were the fruits of conquest. In England, as might be expected, this sort of imitation was much less frequent, and on the whole the English revolutionaries employed a vocabulary of their own. The Jacobin ritual was not without its imitators. At Boston to "impress the tender minds of the rising generations with the precepts of equal liberty" civic cakes inscribed "Liberty and Equality" were distributed to the youth of the town assembled in State Street. The Roman society took on the impressive if exacting title of Gli Emuli di Bruto. Such clubs resorted to methods of bringing pressure to bear on public opinion familiar to students of French Jacobinism. The club at Mainz kept two registers, one bound in red with tricolor edges for patriots, the other bound in black and equipped with chains for those who opposed the revolution. Naturally not a soul signed the black book. One can even distinguish in the following statement from the

Democratic Society of Chittenden County, Vermont, that mixture of fear and assurance characteristic of French Jacobin functionaries: "We are eighty-four citizens—amongst whom are eight members of the Legislature—all the General Officers of the County—the High Sheriff—the majority of the Bench—and all the Bar, except two, *whom prudence has as yet prevented from asking for admission.*" The membership of the clubs outside France although including many humble men seems never to have been without prosperous and distinguished elements. The Rhenish clubs were filled with professors, physicians and merchants. If the English movement numbers poor men like Hardy, it includes clergymen like Tooke; scientists like Priestley; and even noblemen like Grey, Daer and Stanhope. In the Philadelphia society are to be found such names as Rittenhouse, Biddle and Dallas. Finally, political passions, especially in America, were kept at a white heat by the clubs. Washington himself, who blamed them for the Whisky Rebellion, lost his temper with them and spoke of them scornfully as "certain self-created societies" attempting to undermine the government.

These societies, at least in England and in America, were unquestionably influenced by local and national aims and in part twisted French ideas and French fashions to suit themselves. In England parliamentary reform was a specific goal, and the rights of man might come after the rights of Englishmen. In America the quarrel between Hamiltonians and Jeffersonians can certainly not be stated wholly in terms of French politics. The Jeffersonians, for instance, were states' rights men, the French Jacobins ardent centralizers. The agrarian discontent in America was a frontier discontent and a powerful element in the Jeffersonian party. French Jacobinism was almost wholly an urban product. Yet when all these qualifications are made, one is left with a definite impression that Jacobinism in the 1790's was a genuine international movement; that in the various countries it touched it did have a roughly similar program, employed a similar technique of political action, attempted through a similar ritual to create a political faith. No doubt selfish men in all countries exploited this enthusiasm for quite unphilosophical purposes of their own. But for most of the Jacobins in the western world the faith was real and promising. Not until the best days of the Second International was so widespread and so cosmopolitan a movement to appear in Europe. And

Marxian socialism even before the Russian Revolution lacked the freshness and hope of Jacobinism.

France herself began the destruction of this international Jacobinism. The Convention and the Jacobin clubs abandoned their eighteenth century cosmopolitanism for an aggressive policy of national expansion. But France was not alone in feeling this new, democratic union of all men in a patriotic emotion. Triumphant Jacobinism stirred up the new nationalism in the countries it had conquered. Wordsworth, Fichte, Cuoco, to take but a few examples, began a search for a principle to justify their distrust of the once admired revolution. They all ended in a violent and extreme repudiation not merely of Jacobinism but of the ideology, the aspirations, even the fashion and the diction of the century which had produced Jacobinism. By 1815 Jacobinism had everywhere been driven underground—even in America, where Jeffersonian democracy was becoming Jacksonian democracy and the frontier had lost touch with France.

In France indeed Jacobinism survived to appear again at crucial moments in French history. As a type the Jacobin with his anticlericalism, his dislike of the overrich, his moral austerity, his distrust of any government actually existing, his reliance on the individual in economic matters, has existed outside France. If the word is sufficiently diluted it may be used to cover most nineteenth century European republicans. As a movement Jacobinism after having been cut short by Louis Philippe's acceptance of the throne in 1830 did much to create the Revolution of 1848. Here and again in 1871 Jacobinism sometimes collaborated and sometimes found itself at odds with socialism. Jacobinism was characterized by political tactics which came very near direct action, a group consciousness very near class consciousness, a fighting tradition, a devotion to the centralized, bureaucratic state; and Jacobins no doubt helped develop these aspects of modern socialism. But in its support of the small owner, peasant or shopkeeper and in its fervid nationalism it is clearly distinguished from socialism. Nineteenth century liberalism too owes something to Jacobinism, to its confidence in the possibility of a better earthly life for all men, to its belief in the career open to talents, to its insistence that law rests ultimately on morals rather than on power. But the liberal is shocked at the Jacobin's absolute state, his contempt for history, his love of political violence, his intolerant anticlericalism, his disregard for

the rights of minorities. Englishmen like Mill and Acton deny that Jacobinism is liberal and regret that on the continent liberalism is corrupted by Jacobinism. Traditionalism, that of a de Maistre or a Metternich, may seem the complete antithesis of Jacobinism. But Comte's admiration for de Maistre is no mere whim. Both traditionalism and Jacobinism attempt the application of moral absolutes to politics. The absolutes are indeed different, but the temper is the same. Both are authoritarian rather than libertarian, and both are unwilling to admit that experience is real enough to modify their theories. Today Jacobinism, if not dead in France, has achieved its political ends, many of its social and economic ends—France is a land of rough economic equality, but also of economic individualism—has seen church and state separated, has in short turned conformist. The old Jacobin tactics of resistance, the Jacobin methods of pressure, the Jacobin spirit, have passed to the extremists, to the monarchists and the communists.

JACOBS, JOSEPH (1854-1916), Anglo-Jewish historian. Jacobs was born in Sydney, New South Wales, and was educated at Cambridge and Ber-

lin. In 1887 he assisted in organizing the Anglo-Jewish Historical Exhibition which led to the founding of the Jewish Historical Society of England, of which he was one of the first presidents. In 1900 he went to America to edit the *Jewish Encyclopaedia* and he was mainly responsible for its sections on anthropology and the history of the Jews in England. He was for several years professor of history in the Jewish Theological Seminary of New York. In 1888 he toured Spain, surveying material on the history of the Jews in that country and producing a masterly account of his discoveries, which was limited in value because he failed to see many original documents owing to the shortness of his stay in the country. Jacobs' greatest historical work, embodied in articles in the *Jewish Encyclopaedia*, the *Jewish Quarterly Review* and the *Transactions* of the Jewish Historical Society of England and his book *Jews of Angevin England*, concerned the Jews in England before the expulsion of 1290. Despite the fact that he was often careless, had an inadequate knowledge of Hebrew and was given to conjectures inspired by patriotic prejudices he produced work of great value based on long neglected original sources. The results of his labors, still not superseded, are the basis of the known Jewish history of pre-expulsion England. His *Jewish Contributions to Civilization*, although an incomplete fragment of a larger work, is a brilliantly suggestive essay.

Aside from his work in Jewish history Jacobs made a number of interesting anthropological studies of Jews and important contributions to the study of fairy tales and the migration of fables. From 1889 to 1900 he was editor of *Folklore*, the journal of the Folk-lore Society. As editor of the *American Hebrew* from 1906 until his death and in other activities he was a leading figure in contemporary communal affairs, representing on the whole a conservative viewpoint.

JACOBUS. See FOUR DOCTORS.

JACOBY, JOHANN (1805-77), Prussian politician. Jacoby, who throughout his political career continued to practise medicine in his native town of Königsberg, was the outstanding spokesman of East Prussian liberalism, which during the decade preceding 1848 set out, under the spell of Aufklärung and especially of Kantian ideology, to constitutionalize the Prussian monarchy and state and to transform Prussian subjects into free citizens. His pamphlet, *Vier Fragen beantwortet von einem Ostpreussen* (Mannheim 1841), in clearly formulating the demand that Frederick William IV grant the written constitution promised by his father at the close of the War of Liberation, gave a decisive impetus to the movement which culminated in the Revolution of 1848 and the establishment of a constitutional monarchy. As a result of the prosecutions in which the pamphlet involved him Jacoby's prestige was firmly established as one of the outstanding champions of aggressive liberalism. Essentially, however, a doctrinaire, tending to an almost religious fanaticism and to a faith in the categorical imperative as the sovereign rule of political as well as moral conduct, he was not skilled in the more immediate problems of political statesmanship and tactics. Moreover by the time of the revolution he had come to realize the greater importance of social problems as compared with purely political ones. His greatest practical influence was exerted during 1848-49, when as a member of the Prussian National Assembly he played a leading part in formulating the program of the Democrats and advised the Assembly to resist to the utmost the threatened coup d'état. As a member of the delegation sent by the Assembly to the king he expressed his opinion that it had "always been the misfortune of kings not to want to hear the truth." This unguarded outburst tended to prejudice him in the eyes of less thoroughgoing liberals and caused his influence to wane. Jacoby still held fast, however, to his faith in the ultimate victory of democracy in Germany and to his international ideal of a "union of free democratic states." He refused to recognize the Bismarckian empire, since it had been brought about by force without the consent of the people. In 1872 Jacoby joined the Social Democratic party but declined to take an active part in parliamentary life.

GUSTAV MAYER

Zeitung (March 8, 1927) 1-3; Adam, R., "Johann Jacobys politischer Werdegang 1805-40" in *Historische Zeitschrift*, vol. cxliii (1930) 48-76; Meinecke, F., *Weltbürgertum und Nationalstaat* (7th ed. Munich 1928) p. 376-79; Schay, R., *Juden in der deutschen Politik* (Berlin 1929) p. 139-50.

JAHN, FRIEDRICH LUDWIG (1778-1852), German patriot. Jahn together with Ernst Moritz Arndt was the first herald of national democracy in Germany. He traveled through Germany investigating language and folklore and in 1810 published his *Teutsches Volkstum* (new ed. Leipsic 1817), in which he maintained that national peculiarities are indestructible and that foreign interference should be resisted.

In his grief over Germany's humiliation during the Napoleonic wars Jahn strove to awaken the physical and moral energies of the people. He found the means for accomplishing this in the development of physical education. Stimulated by Pestalozzi's educational ideas he grasped the fact that physical exercises are the means of training the perfect man. His aim was not only to steel the body but to form the will and develop a feeling of fellowship. In 1811 he established the Hasenheide athletic grounds near Berlin, where he laid most stress on those exercises which called for practical use and action. Like vom Stein, Jahn recognized the removal of social barriers as of utmost importance for the awakening of national feeling. He thus aimed to unite young people of all classes on the playground for common service, and the grey linen dress which his followers adopted served as a simple uniform suited to wipe out class differences. He was convinced that the community of gymnastics would provide the basis for a common national spirit.

Jahn's exercises and ideas were closely knit up with old Germanic traditions and folklore. He inveighed coarsely against the Jews and all foreigners and his followers adopted a harsh manner. For this reason he aroused wide antagonism and soon too the government came to suspect him as a demagogue and corrupter of youth. The playgrounds were closed and until the Revolution of 1848 gymnastics were forbidden throughout Germany. Jahn himself was arrested and forced to withdraw from public life. The Revolution of 1848 brought him into the Frankfort Assembly and he has since been acclaimed as a hero of the Prussian regeneration.

JAKOB, LUDWIG HEINRICH VON (1759-1827), German economist. Jakob taught in succession philosophy and economics at the University of Halle. In 1806 he was invited to occupy the chair of political economy at the University of Kharkov. In 1816 he returned to Halle, where he spent the remainder of his life.

A disciple of Immanuel Kant and of Adam Smith, Jakob attempted to combine the theories of both. He accepted the principles of economic liberalism, but with Kant asserted the primacy of ethical considerations and assigned to the state a more positive function in furthering the development of society. Jakob recognized the relative character of the principle of free trade and thus anticipated the stage theory of List. While in Russia Jakob carefully studied the efficiency of the serfs and his conclusions anticipated those of later writers on the economy of high wages. His writings on monetary conditions in Russia are of particular value because of their suggestive treatment of foreign exchanges, the effects of paper money and related problems.

JAKŠIĆ, VLADIMIR (1824-99), Serbian statistician. Jakšić studied statistics under Fallati at Tübingen and economics under Rau at Heidelberg. In 1847 he entered the Serbian Ministry of Finance and from 1852 to 1862 taught economics and commercial law in the *lycée* in Belgrade. When the government was finally persuaded to set up an independent department of statistics in 1864 Jakšić became its first director; he re-

mained its leading spirit for over two decades.

Jakšić viewed statistics as an indispensable tool in the rational administration of a country and devoted the major part of his life to the task of collecting and interpreting statistical material bearing on the social and economic development of Serbia. In his *Predlog o ustrojtstvu i programu državne statistike* (Project of the organization and program of government statistics, Belgrade 1850, 2nd ed. 1858) he attempted on the basis of statistical material, part of which he had collected in his studies and part in his extensive tours of European countries, to discover the factors leading to the decline in the national well being. He also formulated in this original work a comprehensive program of social and economic reform for the purpose of ameliorating the political and economic status of his country. Jakšić is credited with the organization of a systematic meteorological observation service. His interest in meteorology may be traced to Rau, who demonstrated the practical value of the knowledge of climatic conditions in agriculture.

JAMÁL U'D-DÍN AL-ÁFGHÁNÍ (1838 or 1839-97), Moslem reformer. Jamál was born probably either in Afghanistan or in Persia. He studied at the famous madrasah of Bokhara, where he acquired a remarkable knowledge of all the Moslem sciences and especially of mediaeval Moslem theology and philosophy. He then traveled widely through the Islamic countries, visiting India, Arabia and Turkey; in 1871 he settled in Egypt, where he taught at the university of Al-Azhár. There he won considerable influence over the youth of Egypt identifying himself with the religious reform and the incipient Young Egyptian movements; as a result he incurred the dislike of both the orthodox clergy and the European powers and was forced to leave Egypt in 1879. After three years in India he lived from 1882 until about 1889 in London, Paris and St. Petersburg, writing for the leading newspapers. In Paris he published, together with

Muḥammad 'Abdu, who had been his pupil and follower at Al-Azhár and became later the famous Mufth' of Egypt, an Arab weekly, *al-'Urwatu' l-Wuthqá*. This journal criticized English policy in Moslem countries, and although only eighteen numbers were published its influence was widespread. From 1889 to about 1891 Jamál lived in Persia, where he worked intensively, arousing a reform movement which subsequently gave rise to the Persian revolution. The last years of his life were spent in Constantinople on a pension from Abdul-Hamid, the Ottoman sultan, who was interested in Jamál because of his own pan-Islamic activities.

Jamál was one of the earliest thinkers and leaders of the nineteenth century Moslem and Asiatic renaissance. He recognized the threat to the East inherent in the material superiority of the West; believing, however, that Islam was not a rigid system but one capable of adaptation to existing spiritual and temporal needs, he held that the slumbering forces of the Islamic world could be awakened to new life by the devoted efforts of the younger generation of Moslems. He urged the union of all Islamic states under a single caliphate capable of liberating them from European exploitation and influence. He also expounded the doctrine that Islam aims at popular government.

His vast knowledge, his incessant endeavors to revive the splendor of Islam through the awakening of Moslem youth and his courageous stand against European aggression and oriental despotism made him extremely influential and he may be rightly called the father of all subsequent renaissance, pan-Islamic and nationalistic movements in Egypt and in the Moslem East. He was, like the European figures of the early Renaissance, scarcely conscious of the implications of the new era; nevertheless, he sowed in many lands the seeds of change which a few decades later blossomed in a way unforeseen and perhaps undesired by the sower.

HANS KOHN

JAMES I (1566-1625), king of Great Britain and Ireland and king of Scotland as James VI. James was the son of Mary Queen of Scots by her second husband, Henry, Lord Darnley. He succeeded to the Scottish throne as an infant,

through the enforced abdication of his mother. His governance of Scotland was a grim school of experience with a turbulent nobility on one side and a domineering priesthood on the other. Its effect upon him is set out in the *Basilikon Doron* (Edinburgh 1599), a treatise on the duties of kingship which he published for the instruction of his elder son, Henry, and in his *True Law of Free Monarchies* (Edinburgh 1598), which he published anonymously. He argued that kings were chosen by God to govern and that the duty of subjects is merely to obey. The king is above the law but although responsible to God alone he should concern himself to obey it unless the well being of his subjects demands otherwise. In his view even a wicked king is entitled to the allegiance of his people; only God may punish him.

In 1603 the death of Elizabeth brought him to the English throne. He showed little insight into the character of his position. Impressed by the despotism of the Tudors, he did not realize its basis in popular consent. He was led accordingly by his high notions of prerogative into quarrels with Parliament, the Puritans, the Roman Catholics and, in the person of Sir Edward Coke, the courts of law. James' mistake was not to realize, first, that he was a foreigner to his new subjects and, second, that the whole character of parliamentary institutions was changing. His speeches to his different parliaments all show an unwillingness to recognize the new atmosphere. He took the view that the king is the shepherd of the flock, the father of his people; and he sought to make of Parliament rather a body to advise and support his policies than one with authority to initiate. Had he been wise and successful he might have enforced his doctrine, but he was weak and vacillating and given to the cultivation of favorites who lacked the ability necessary for government. He was, however, a man of considerable learning, not without foresight and averse to extremes. His learning is manifested with some distinction in his *Apology for the Oath of Allegiance* (London 1607), in which he defended the legislation which followed upon the discovery of the Gunpowder Plot. A long controversy followed his book, in which the protagonist on the other side was the eminent Jesuit Bellarmine. James maintained with much ability the danger to monarchical sovereignty of the allegiance claimed by popes from their subjects.

JAMES OF VITERBO (Giacomo Capocci da Viterbo) (c. 1255-1308), Italian scholastic theologian and political theorist. James of Viterbo was an Augustinian monk and a pupil of the famous Augustinian general Aegidius Romanus. He was educated in Paris and in 1300 became rector of the Studium Generale of the Neapolitan Augustinians. In 1302 through the favor of King Charles II of Naples and of Boniface VIII he was appointed first archbishop of Benevento and a few months later archbishop of Naples, in which capacity he remained until his death. Most of his theological writings are still unprinted, but his tract on ecclesiastical politics, *De regimine christiano*, has recently become especially well known. Recognized as the oldest scientific treatment of the Catholic doctrine of the church and of the papacy, the *De regimine* was written in the summer of 1302 in the midst of the struggle between Boniface VIII and Philip the Fair of France. It belongs among those curialistic writings which paved the way for the issue of the bull *Unam sanctam* on November 18, 1302, but it shows hardly a trace of controversial writing. It is divided into two sections, "De regni ecclesiastici gloria," in which the author analyzes the nature of Christian society, of the state and of royal power, and "De potentia Christi regis et sui vicarii," in which he develops his ideas concerning the authority of the papacy. By a unique combination of the mystical Augustinian notion of the divine state with the natural law doctrines of Aristotle he arrives at the idea that the true and perfect state is the church. The church is the social—which James does not distinguish from the political—community of mankind, the universal *res publica*. The pope as head of the church and as Christ's vicar inherits the spiritual royal power of Christ, which includes both ecclesiastical and temporal authorities. The emphasis of James' discussion of the papacy is placed throughout not upon its specifically sacerdotal attributes but upon its sovereignty, a sovereignty

in which religious and mystical elements are inseparably fused in the mediaeval manner with temporal and political.

In its conclusions James' *De regimine christiano* bears a close relation to the slightly earlier *De ecclesiastica potestate* of his teacher Aegidius Romanus. But without sacrificing Aegidius' extreme position with regard to the temporal authority of the papacy James consistently shows more deference than does Aegidius to the secular state. Aegidius holds that the authority of the prince is unlawful and evil unless derived from the church; James recognizes a natural and human justification for the existence of the state irrespective of its relation to the church. The only perfect authority is, however, the spiritual regal power of the absolute pope, whose kingdom is superimposed upon all states. He is the king of kings and all human institutions must submit to him, who alone can bestow the divine elements necessary to complete the human order. James' tract had considerable influence on subsequent writers, particularly upon those who participated in the conflict between Pope John XXII and Louis of Bavaria, notably Alexander of St. Elpidio and Alvarus Pelagius.

JAMES, WILLIAM (1842-1910), American psychologist and philosopher. James, who had the cultural advantages which prosperity provides, considered his early education, which was desultory and spread over schools in France, Switzerland and the United States, as worthless. The most important influence upon his childhood and youth was his father, Henry James the elder, whose idiosyncratic speculations about man and nature derived from Swedenborg constituted the permanent intellectual atmosphere of the Jamesian household. Combined with them was an antisectarian liberalism in religion, a per-

fectionism in politics and a general utopianism in social outlook.

In 1865 James interrupted his scientific studies at Harvard to go with Agassiz to the Amazon, but finding the climate bad for his health and the work not to his liking he returned to continue his studies. After a term he went to Germany, where he spent eighteen months in the study of medicine and in a struggle with a depression so acute as to lead to notions of suicide. When he resumed his schooling at Harvard he was still ill. He obtained his medical degree but could not practise. During this period he fell into a phobia with which was associated the doctrine of materialistic determinism. All his studies in the sciences had made the doctrine seem logically and practically inevitable; as applied to himself it made him afraid. A reading of Renouvier on free will started a train of thought of which all his subsequent work was elaboration and development. From that time on his health improved.

After a few years as instructor of anatomy and physiology at Harvard, James (from 1875 onward) taught psychology and philosophy. His treatment transformed both subjects from "mental and moral philosophy," verbal, abstract and related neither to living experience nor to the realities of nature and human nature, into specific, concrete, vital and new observations of the qualities of men and the nature of things. The general view which these observations comprise cannot be called a system. They presume rather an attitude of mind and a method and the perspectives of the universe and the insight into human behavior which the attitude defines and the method enables. The attitude rejects the closed, exclusive, self-consistent unity which systems require. It permits an openness to every item of experience, an acknowledgment that every event or belief or opinion which presents a claim to reality or truth has the right to make its claim good if it can, at its own risk. It is an empirical attitude, but the empiricism is radical; no idea, no event, no thing or relation is rejected or classified a priori. Its status is eventual; it receives its chance to make good or fail. The method, which James called pragmatism, is the process or technique of making good or failing. It is a summary of the observation that throughout human experience the reality or illusoriness of things and ideas, their goodness or badness, their truth or falsehood, are not primary but eventual; not the stations or qualities they are born with, but the positions and powers they

win to—the accumulation of their consequences, not the expenditure of their endowment.

The world we live in consequently is for James a world of change and chance, of plurality, variety and variation, of chaos and novelty and struggle. He sees the laws of nature not as eternal principles but as acquired and changing habits of things. He sees the qualities of men as variables born of chance, enabling them to live together in and with and upon their environment, or not. Every human trait operates as instrument in the individual's struggle to live; each is validated or condemned by its effects upon this struggle. The individual is the primary and fundamental factor, the *terminus a quo* and the *terminus ad quem* of societies. Societies are eventual; folkways and institutions are only acquired habits of grouping, changing and changeable. The process of history is the sum of the changes they undergo. These changes are always accomplished by individuals. Social like mental evolution is the flux of the selective action of the environment upon individuals and of the transforming action of individuals upon the environment. Individuals are data, like other spontaneous variations, and their interaction with society is similar. History takes new turns when individuals decide between alternatives. Nations, arts, religions, science itself, are all given direction and character by the free initiative, the effort and activity of individuals. Give individuality a chance, enable initiative and freedom, and life and growth are assured to society.

While the current trend of the physical sciences is largely in the direction of James' view of the nature of things, the social sciences have moved farther and farther from it. The application of the quantitative method has been extended from the processes of economics to the activities of the mind; measurement of intelligence paces measurement of interest rates and business cycles. In all the social sciences the statistician's correlations are sought as surrogates for the operative cause in social change. The abstract average is set up for study in place of the living individual and his concrete give and take with his living environment. For the abstractionism of this procedure, the Jamesian attitude and the pragmatic method, with their emphases on individuality, spontaneity and novelty, their stress on free initiative and real action in time, offer salutary correctives.

M., *William James and Henri Bergson* (Chicago 1914).

JAMESON, ANNABROWNELL (1794-1860), British writer and feminist. Perhaps more than any other person of her time Mrs. Jameson exposed the great discrepancy between the traditional picture of the position of the Victorian middle class woman and the actual social and economic status of large masses of self-supporting middle and lower class women in the post-Napoleonic reconstruction period. From her own experiences as governess and later, after separation from her husband, as hack writer and from a careful study of the reports of the Children's Commission of 1842-43 she was able in her writings to bear witness to the sorry position not only of women in factories and the sweated trades but of those who were in the overcrowded and underpaid occupations of governess and dressmaker. She saw clearly the necessity of new outlets for the self-supporting middle class women and at the age of sixty-two, inspired by the work of Florence Nightingale in the Crimea, visited hospitals and charitable institutions in Germany and France to collect information about the training of workers, which she then promulgated in lectures later published as *Sisters of Charity Catholic and Protestant Abroad and at Home* (London 1855) and *The Communion of Labour* (London 1856). She was the first person to sign the petition to Parliament in 1856 for a married women's property act to protect women's earnings. Without having formulated a clear cut philosophy Mrs. Jameson's "sound thought, fearlessly expressed" made her a forerunner of feminism.

Consult: Macpherson, Geraldine, *Memoirs of the Life of Anna Jameson* (London 1878); Neff, W. F., *Victorian Working Women* (New York 1929).

JANET, PAUL (1823-99), French philosopher and historian. After graduating from the École Normale Supérieure Janet was for a time secretary to Victor Cousin. Appointed in 1848 to the

University of Strasbourg, he devoted himself to the history of political and moral philosophy from its remote origins in China and India up to the French Revolution. The result of these studies was his great work on political science, *Histoire de la philosophie morale et politique dans l'antiquité et dans les temps modernes* (2 vols., Paris 1858), which appeared subsequently in several editions (the last of which was ed. by G. Picot, 2 vols., Paris 1913) with the title *Histoire de la science politique dans ses rapports avec la morale*. This work has remained a model of clear exposition and impartial judgment. It was followed by a series of penetrating studies including *La philosophie de la Révolution française* (Paris 1875, 4th ed. 1892), *Origines du socialisme contemporain* (Paris 1883) and *Saint-Simon et le saint-simonisme* (Paris 1878), taken from his popular courses at the École Libre des Sciences Politiques. In 1889 appeared his *Centenaire de 1789, Histoire de la Révolution française* (Paris). Janet justified the rights of man, recalling that France did not invent them but borrowed them from America—although the French formulated the philosophy, it was the Americans who introduced the rights politically—and demonstrating at the same time that they corresponded to concrete needs. He held that the principles of the revolution should not be condemned because of the excesses for which they may have been the pretext and that the task remaining was that of better adaptation of means to ends.

The same inspiration is found in Janet's speculative works, which he wrote after his appointment in 1864 as professor of the history of philosophy at the Sorbonne. As he said upon the publication of his *Principes de métaphysique et de psychologie* (2 vols., Paris 1897), he was never a "peevish and frightened" opponent of new systems; on the contrary, he was sympathetic and tolerant to new ideas without, however, sacrificing anything of his fidelity to *philosophia perennis* or of his critical independence. This proud profession of faith explains the lasting success of his chief work, *Les causes finales* (Paris 1876, 2nd ed. 1882; English translation, 2nd ed. Edinburgh 1883, with preface by Robert Flint), which appeared after the publication of *The Origin of Species*. In this work Janet asserts that he has based his ideas only on facts in order to safeguard "the immanence in the natural world of a purposiveness which in turn is to be understood by its relation to a transcendent end." Janet's other works include *La morale* (Paris 1874, 2nd ed. 1887; tr. by M.

Chapman, New York 1883), *Fénelon* (Paris 1892; tr. by V. Leuliette, London 1914), *La famille* (Paris 1855, 5th ed. 1864), *La philosophie du bonheur* (Paris 1863), various publications within the domain of philosophy and literature and academic handbooks for the teaching of philosophy and the history of philosophy.

Consult: Bergson, Henri, "Principes de métaphysique et de psychologie par Paul Janet" in *Revue philosophique*, vol. xlv (1897) 525-51; Séailles, Gabriel, in *Revue politique et littéraire, Revue bleue*, 4th ser., vol. xi (1899) 65-74; Picot, Georges, "Notice historique . . . de M. Paul Janet" in *Académie des Sciences Morales et Politiques, Séances et travaux*, n.s., vol. lix (1903) 18-55; École Normale Supérieure, Association Amicale des Anciens Élèves, *Annuaire* (1900) 31-47.

JANNET, CLAUDIO (1844-94), French economist. Jannet studied law in Provence, where he became the friend and disciple of Frédéric Le Play. At the suggestion of the latter he went to Paris, where at the newly founded Institut Catholique de Paris he was given the chair of political economy, which he held until his death.

Jannet represented the conservative Catholic wing in French economic thought. His views were elaborated in *Le socialisme d'état et la réforme sociale* (Paris 1889, 2nd ed. 1890) and *Le capital, la spéculation et la finance aux XIX^e siècle* (Paris 1892). In common with the socialists of the chair he stressed the ethical basis of economics but differed from them in that he rigorously opposed the intervention of the state in the economic activities of the people. He was aware of the necessity for social action to remedy some of the evils of unrestricted economic individualism but believed that such action should be undertaken by private or communal agencies rather than by the state. In his method Jannet occupied a position approaching that of the inductive school; he stressed the necessity of studying economic phenomena in the light of the political and cultural milieu of the respective periods but recognized the universal validity of fundamental economic principles. Jannet also won recognition by his study made during a long visit to the United States entitled *Les États-Unis contemporains* (Paris 1876; 4th ed., 2 vols., 1889). In his work Jannet described the public institutions in the United States after the Civil War, pointed out the moral forces holding in check the dissolving elements and concluded with an avowal of faith in the future of American democracy.

JEAN AUBURTIN

JANSENISM was a movement within the Catholic church which took form in the seventeenth century around the theological writings and doctrines of the Flemish bishop Cornelis Jansen (1585-1638). The movement was confined principally to France, where it had an important and many sided influence on social and political life in the seventeenth and eighteenth centuries.

From a theological point of view Jansenism denoted a return to Augustinianism in opposition to the Pelagianism and semi-Pelagianism which the Jansenists attributed to the Jesuits and particularly to the Spanish theologian Molina. To the Jansenists the belief that man can achieve salvation through his own powers was equivalent to infringing upon the will of God. They thus defended the *causa dei* against the man who resists the divine will. Their God was a ruler with unlimited power, who was under no obligation to man and whose will must be obeyed unconditionally.

The controversies between the Jansenists and the Jesuits concerning the omnipotence of God and the rights of man offer certain analogies to the political discussions which arose later about the nature and limits of secular authority. The Jesuit conception of God's relation to man, which grants man certain rights and demands justice from God, is nearer to modern ideas of freedom. The Jansenists believed that man, who is fundamentally corrupted by original sin, can only hope for God's mercy. Man, they asserted, is wicked; left to himself he can only commit evil. For the Jesuits, on the other hand, man as such is not a sinner. Whether he acts morally or immorally depends upon his free will. In contradistinction to the Jansenists' utterly pessimistic view of human nature the Jesuits revealed a more optimistic attitude, one suggestive of the ideas of the Enlightenment and of Rousseau, who believed that man is fundamentally good.

But while the Jesuits in many ways anticipated modern tendencies, the lay communities sympathized chiefly with the Jansenists for several reasons. The Jansenists maintained that God must be obeyed in preference to man, and they were accordingly ready to oppose the public authorities whenever they had reason to believe that the latter were requiring citizens to act in a manner incompatible with true faith and the duties imposed by it upon every Christian. This defiant attitude gained for them the favor of the educated classes, who in theological form thus gave expression to their own claims against the public authorities. Furthermore the Jansen-

ists offered the layman opportunities to acquire an understanding of the grounds underlying their theological tenets. Their polemical writings enabled non-theologians to participate in theological discussions. On the basis of the texts cited in these controversies it became possible for the layman to make an independent decision as to which side was right. To win the layman over to their cause became in fact the great concern of the Jansenists, for with his support they could resist more effectively the attacks of the state and the church.

Under the influence of the Jansenist polemical writings religious questions became instrumental in creating a public opinion. Every educated person sooner or later took sides in the controversies that raged between the two parties. Theology became a matter of public interest and the layman acquired the right to utter an opinion in a field that had been formerly reserved for the clergy. To this the church and the state were opposed, while the Jansenists were glad to see the layman come out in defense of his faith.

These matters concerning which the educated layman was now given an opportunity to express his opinions were, in view of the interlocking of church and state, of the utmost importance for public life; and the discussions concerning them may be considered as constituting a theological forum of public opinion preceding and in a certain sense preparing for the philosophical and political forums of later days. Philosophers were later to dismiss all theological controversies as sterile, but such discussions were of great significance in the development of the educated middle classes. These controversies did not of course involve any free exchange of opinions such as that carried on by the philosophers of the Enlightenment. The final court of appeal was the Catholic tradition. In terms of this tradition the educated layman with the aid of the Jansenist theologians was in a position to detect violations in decisions of the state and church. The Jansenists regarded tradition as opposed to the authority of the temporary holders of ecclesiastical power. It was to tradition so interpreted and especially to St. Augustine that they appealed in their contest with the Jesuits, whom they believed to advocate a new and consequently false theology. They emphasized repeatedly that nothing must be taught which stands in contradiction to the inalterable basic doctrines of the church.

It is this defense of established basic doctrines that accounts for the intellectual affinity be-

tween the Jansenists and the *parlements*, which were the champions of legal traditions, particularly in the field of canon law. Both had the same adversaries: the absolute kings, who did not care for the old rights; the representatives of the Roman papacy; and especially the Jesuits, who wanted to bestow unlimited authority upon the pope. The same reason explains why in the eighteenth century the Jansenists combated both the Jesuits and the philosophers of the Enlightenment, who in their eyes exhibited a similar intellectual outlook, and began to play the role of a conservative opposition in the ecclesiastic and religious field. They gradually became the party of the old belief, opposing all modern tendencies which endeavored in some way or other to mitigate the harshness and austerity of this faith.

This evolution of Jansenism from a religious community which had grown up in the convent of Port-Royal into a party which penetrated into wide circles had a profound effect upon the public life of France. Jansenism was not a sect, as was claimed by its adversaries. It was neither an order, like the Jesuits, nor a publicly recognized institution, like the *parlements*, but rather an organization which developed freely on the basis of common convictions and which had certain characteristics of modern political parties. This became particularly evident when the Jansenists began to publish a periodical of their own: the *Nouvelles ecclésiastiques* (1728-1803). The magazine owed its origin to the controversies caused by the publication of the bull *Unigenitus* (1713), which condemned the 101 propositions in the work of the Jansenist Quesnel: *Le Nouveau Testament en français avec des réflexions morales*. The *Nouvelles ecclésiastiques* gradually began to make critical comments on all the daily occurrences that took place in the life of the church. The attitude of opposition which was thus popularized by the magazine contributed to the preparation of the lower clergy for the important role they were to play in the first days of the French Revolution. By that time, it is true, theological controversies had already lost much of their original interest; but the Jansenist longing for a pure Christianity aloof from all secular concessions persisted and continued to inspire the lower clergy with a desire to reform the church.

The Jansenists also made an important contribution to the development of a social morality, achieving their first great victory in the publication of Pascal's *Lettres provinciales* in 1656.

Combating the lax moral views of the casuists they represented—especially in the personality of Arnauld—the type of the *honnête homme*, whose life was in accordance with his views.

It would, however, be erroneous to see in the Jansenists simply the opponents and in the Jesuits the adherents of casuistry and probabilism. The Jesuits too often brought to light a positively oriented social morality significant for modern economic life. The most outstanding Jesuit representative of this tendency was the preacher Bourdaloue, whose counterpart on the Jansenist side was Nicole, the author of the *Essais de morale*. In both can be found vigorous elements of an urban middle class morality. Nicole maintained that the mode of life of this class lent itself better to Christian ideals than did that of the courtiers. Poverty, on the other hand, could become dangerous for a Christian, who was therefore advised to lead a modest bourgeois life, to regulate his conduct in accordance with firm principles, to fulfil his duties loyally, to be conscious of the sinfulness of man and never to try to rise above his own class.

The social morality of the Jansenists proved to be a stimulus to the growth of the ethical consciousness of the urban middle class. Certain of their tendencies led to the development of the bourgeois type of Christian, the type who performs his daily activities with the consciousness that he is pursuing moral ends and that he is doing God's work on earth. The Jansenist social morality could not, however, continue to satisfy the demands of the middle class as the latter became prosperous and acquired social prestige. It was not adapted to the spirit of the new economic life. In glorifying the self-sufficiency of the lower middle class the Jansenist morality was unable to justify the aspirations of the upper bourgeoisie for power and wealth. It was reserved for the philosophers of the Enlightenment to supply the latter with appropriate values and ideas.

JANSSEN, JOHANNES (1829-91), German historian. After studying history and theology Janssen became professor in the *Gymnasium* at Frankfort on the Main. His importance, which is still considerable, is based on his chief work, *Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters* (8 vols., Freiburg i. Br. 1877-94; new ed. by L. Pastor, 1913-24; tr. by M. A. Mitchell and A. M. Christie, 16 vols., London 1896-1910, with index 1925). This book was in many respects not only original but epoch making. The account was built up almost exclusively on contemporary sources, which Janssen harmonized into a mosaic of extraordinarily vivid representations. The narrow limits of the hitherto predominantly political view of history were extended to include a universal examination of all historical spheres of life. The masses, almost overlooked by Ranke and his school, advanced to the foreground and became the deciding factor in historical action. The chief emphasis was placed no longer on political and military events but on the aspects of social and cultural life. Thus, along with Freytag and later Lamprecht, Janssen blazed the trail in social, economic and cultural history in Germany. He was entirely original even in his analysis of the course of history. Like Döllinger before him he grounded his work scientifically on the thesis today almost universally accepted that German culture and the German people reached the peak of their development not in the period of the Reformation but in that of the later Middle Ages. He showed that the sixteenth century was a period of decline, which reached its lowest point in the Thirty Years' War. Although this complete reversal of the official historical picture was sharply attacked, Janssen's history had a wider sale in Germany than any previous history of similar scope.

Janssen, a Catholic, had been urged to make this complete revision in the evaluation of the Protestant revolt by his Protestant teacher and friend, Friedrich Böhmer. Like Böhmer, Janssen supported in opposition to the "Prussian" school of historians that interpretation of German history which saw in the increase of the territorial power of the princes and in the decline of the idea of a universal empire after the sixteenth century the greatest peril for the development of Germany.

JARVIS, EDWARD (1803-84), American statistician and physician. Jarvis was president of the American Statistical Association from 1852 to 1882 and active in the improvement of the federal census during this period. After a few years of general medical practise he devoted himself increasingly to mental diseases. In this connection he became interested in the reports of the census of 1840 and discovered gross errors in the statistics of insanity among northern Negroes. According to the reports many northern towns had more Negro lunatics than the total colored population. Jarvis exposed the errors in a pamphlet, *Insanity among the Coloured Population of the Free States* (Philadelphia 1844), and called the matter to the attention of the American Statistical Association, which requested Congress to take action to correct the errors. The erroneous figures, however, had been widely used as proslavery propaganda and Congress took no action. Jarvis assisted unofficially in the census of 1850 and was appointed by the secretary of the interior to prepare the section on mortality statistics of the census of 1860, which he put on a more comprehensive and scientific basis, and worked on the census of 1870. He also served as a member of several commissions on lunacy, public health and statistics and published a number of reports on those subjects. The American Statistical Association in 1860 sent him as its representative to the fourth International Statistical Congress in London. On his retirement in 1883 he was made president emeritus of the association.

JASTROW, MORRIS (1861-1921), American orientalist. Jastrow was born in Poland. His father was a Talmudic scholar who, expelled because of his sympathies with the Polish revolutionists of 1863, emigrated to the United States and in 1866 became rabbi of a Philadelphia congregation. After graduating from the University of Pennsylvania Jastrow studied under the most distinguished European orientlists and the pioneers of the science of comparative religion. He became lecturer in Semitics in his university and later professor; he was university librarian from 1898 to 1919. Jastrow showed remarkable acumen and versatility in almost all lines of Semitic studies. For his doctorate he published a work of the Jewish-Arabic grammarian Hayyuj. His Biblical studies covered a wide range in philology and criticism, culminating in a number of critical translations which illustrated his theory that the Bible reflected the ideas of a series of writers with diverse points of view. He early distinguished himself as an Assyriologist, particularly by his studies in Babylonian religion, which were among the first authoritative works on the subject. He cast much light on the social history of Babylon and on the relation between the Babylonian and Hebrew cults. Jastrow was an American pioneer in the study of the history of religion and the prime mover in obtaining recognition for the new science. He was a founder and the secretary of the Committee of American Lectures on the History of Religion, which published an important series of volumes, and edited a series of notable textbooks on the religions of the world; he stimulated considerable scholarly work among his students.

JAURÈS, JEAN (1859-1914), French socialist leader, statesman and historian. Jaurès studied at the École Normale Supérieure and after several years of teaching at Albi and at Toulouse, where he was professor of philosophy, he devoted himself to politics and was elected deputy in 1885. He began as a moderate republican but was very sensitive to advanced ideas. He soon left the moderate republican party of the left

center to become one of the most brilliant leaders of the socialist groups of the Chamber along with Millerand, Jules Guesde and Édouard Vaillant. After his defeat at the election of 1898 he devoted himself entirely to socialist activity. He directed with great success the socialist organ, the *Petite république*, and collaborated on the doctrinal review of reformist socialism, the *Revue socialiste*, founded by Benoît Malon in 1885. In 1904 he founded a newspaper entitled *Humanité* in which until his death he defended his ideas and his socialist method and conducted a vigorous campaign for world peace against French nationalism and European imperialism.

Jaurès can be considered the perfect type of orator. He appealed at once to the feelings, to the reason and to the aesthetic sense. The form of his speeches was harmonious and distinguished, his learning wide and deep, his persuasive force very great. In his speeches he appeared at once impassioned and convincing, the leader of his party and a prophetic statesman. Great charm and great interest characterized his oratory; all of his listeners, even his opponents, were affected by the majesty of his words, by the clarity and solidity of his arguments, by the richness of his images. He deduced his socialism, which was essentially reformist and evolutionist, from democratic ideas. He considered social reform, the socialization of capitalist property, as the logical consequence of political democratic equality. Socialism thus becomes an economic democracy. The people will advance from political sovereignty to economic sovereignty; they will become masters of the entire nationalized wealth. Jaurès considered these reforms not only as a partial amelioration of the economic situation of the working class but as steps toward the social revolution. The reforms added one to another will end in an organic transformation of society. Jaurès recognized the class struggle as a historical fact and emphasized on every occasion the moral grandeur of the social revolution, which he wished to see take place without violence as a result of the concentrated force of the revolutionary proletariat and advanced democracy.

Jaurès was profoundly idealistic. He recognized the scientific and historical value of Marxian ideas; he admitted the historical role of the proletariat as the fundamental agent of the social transformation but sought to reconcile Marxist materialism with his own idealism. In his *Histoire socialiste de la Révolution française* (new ed. by A. Mathiez, 8 vols., Paris 1922-24; originally

published as vols. i-iv of *Histoire socialiste, 1789-1900*, 13 vols., Paris 1901-09), one of the most significant economic interpretations of the revolution, he attempted to reconcile the sociological history of Marx with the heroic and dramatic history of Plutarch and Michelet.

Jaurès was essentially a pacifist and internationalist. In his campaign during the Dreyfus affair, throughout which he heroically combated the reactionary chauvinism of the clergy and the military in the period from 1898 to 1902, he displayed his brilliant qualities as an orator and man of action. Although he always exalted the French national genius he recognized the same right to exist on the part of all the other nationalities, which form according to the Hegelian formula necessary "moments" in the golden chain of humanity.

Playing a preponderant role in the international socialist congresses Jaurès, attacked by the left wing of the Second International (Bebel, Jules Guesde and others) and supported by its center (Victor Adler, Émile Vandervelde), secured at the Congress of Amsterdam in 1904 the unification of numerous socialist groups in France. This had been the ideal of his life and corresponded with his philosophical and social conceptions, which might be characterized in general as an evolutionary pantheism in which the idea of unity predominates. This idea of unity reappeared in all his political and social activity based on solidarity and the interpenetration of all advanced ideas. He constructed the synthesis of socialism, democracy and free thought. An apostle of secularism, he was one of the initiators of the separation of church and state in France. Combining a deep emotionalism with a cultivated intelligence Jaurès was a living synthesis who sought constantly to reconcile opposites and to create a harmonious mankind.

This was his strength but also his weakness, for he believed too deeply in the goodness of men and things. Surrounded by hatred and by nationalistic enmity, he was careless of his own security.

On July 25, 1914, Jaurès delivered a remarkable speech at Lyons, in which he stated the responsibility of France as well as of the other capitalist countries in the catastrophe which was about to occur. On July 31 on the eve of the declaration of the World War he was assassinated.

JAVID, MAHMAD (1876-1926), Turkish statesman. Javid Bey was born a *dunmeh*, a member of a Salonika group of Spanish-Jewish origin which had been converted to Islam. He studied in Istanbul and worked as a bank clerk, translator and professor of economics. He became interested in the Young Turks and was a member of the inner Committee of Union and Progress at the outbreak of the revolution of 1908. Although the spectacular figure in the uprising was Enver Pasha, it was Javid and Talaat who really sustained and directed it.

After the Young Turks came into power Javid achieved success as a financial administrator. He became a deputy in parliament, reporter of the budget committee and in 1909 minister of finance. He established a finance department on western lines and, refusing a French loan because its terms included French intervention in Turkish finances, arranged in 1910 a loan of \$30,000,000 with the Deutsche Bank. In 1911 he was forced to resign but was reappointed after the First Balkan War and helped with negotiations concerning railway concessions and loans.

He strove to keep Turkey neutral in 1914 and resigned when war became inevitable. In 1917 he was again appointed minister of finance and through his financial arrangements he kept Turkey comparatively free of burdensome war debts. He fled after the Armistice but returned in 1922 and became Turkish representative on the Public Debt Council. At the Lausanne Conference he was instrumental in preventing French financial control of Turkey.

After the triumph of Kemal, Javid presided over a secret conference of surviving Young Turk leaders, who drew up plans for a progressive party. The discovery in 1926 of a plot to kill Mustafa Kemal led to Javid's arrest; together with a number of others charged with conspiring to overthrow the government forcibly he was condemned and executed.

JAWORSKI, WŁADYSŁAW LEOPOLD (1865–1930), Polish jurist and social philosopher. Jaworski was professor of law at the University of Cracow. He served for some time as a member of the Reichsrat in Vienna and during the World War he headed the Naczelny Komitet Narodowy (Supreme National Committee), which represented the Polish cause before the Central Powers.

Like many of his generation Jaworski started out as a rationalist in philosophy, an individualist in social theory and a relativist in ethics; however, he soon perceived the limitations of these views and through an intensive study of Plato, Aquinas, Vaihinger and Spann arrived at a universalist-romanticist conception of society with Christian ethics at its base. His concrete contributions were in the field of law. Despite his early opposition to the predominant tendency of his time to regard legal problems from a purely historical and dogmatic point of view he became known as a brilliant representative of legal dogmatism through his works on the law of mortgages and on land registers. Dissatisfied, he turned to administrative and public law and to the philosophy of law. He became an adherent of Kelsen's school but differed from Kelsen in his acceptance of absolute values. His later studies in private and public law are clearly imbued with his social attitude. Even private law, Jaworski held, deals with social phenomena. There is one group of situations which are the result of the life of men in society, but they are after all subject to the control of individuals through the agencies of political life. There is another group of situations that originate in individual aims, but these are nevertheless controlled by the state whenever an individual asks for its cooperation. The norms of the first group are the objects of public law, while those of the second are the objects of private law.

In his project for an agrarian code, published several years before his death, Jaworski endeavored to put his theoretical views into practise. The basic idea of present day land reform in Poland is the creation of the largest possible number of farms providing adequate means of livelihood for single families. According to Jaworski, although this idea belonged to economics rather than to jurisprudence it had to be translated into legal terminology. This translation Jaworski accomplished by introducing into his code the pragmatic idea of "the unit of agricultural enterprise." Since the object of the law is to insure not possession but a definite kind of

organized activity, it was included in the domain of administrative rather than private law. Jaworski also drew up a proposed draft for a Polish constitution.

JAY, JOHN (1745–1829), American diplomatist, statesman and jurist. Jay was serving as member of the Continental Congress when in 1777 he was recalled to aid in drafting a constitution for New York state, the first of the new constitutions to provide for the election of governor by popular vote. In 1779 he served as president of the Continental Congress until he was chosen to negotiate with Spain a treaty which should give the United States among other things free navigation of the Mississippi and a loan. The negotiations proving fruitless, he was transferred in 1782 to Paris as one of the commissioners to arrange peace with Great Britain. He became suspicious of France, perhaps without entire justification, and was largely responsible for the decision to conclude independently of France and contrary to the instructions of Congress the preliminary peace treaty of 1782. As secretary of foreign affairs from 1784 to 1789 he was engaged chiefly in carrying on prolonged although unsuccessful negotiations with Spain over boundaries and the Mississippi question. He urged a revision of the Articles of Confederation, favored a complete separation of legislative, executive and judicial powers and a system of checks and balances and contributed to the *Federalist* (1787–88) five articles, all but four on foreign relations. In 1789 he became the first chief justice of the Supreme Court; the most important decision during his term of office was that of *Chisholm v. Georgia* [2 U. S. 419 (1792)], which affirmed the right of a citizen of one state to sue another state in a federal court—a doctrine later set aside by the Eleventh Amendment (1798). The unsatisfactory provisions of the treaty which he negotiated with Great Britain in 1794, particularly those regarding impressment and West India trade, caused him to be for a time bitterly denounced, especially by the suspicious Anglophobes. He resigned the chief justiceship in 1795, was elected governor of New York

and served in that office until 1801, when he retired to private life. A Federalist in politics, his temperament and social position made him a moderate conservative with democratic sympathies.

JEFFERSON, THOMAS (1743-1826), third president of the United States. After completing his course of study at William and Mary College Jefferson took over and enlarged his father's estate in Albermarle county, Virginia. He practised law until 1774 and from 1769 to 1775 represented his county in the Virginia legislature. Elected to the second Continental Congress, he drafted the Declaration of Independence; but shortly afterward he returned to the Virginia legislature to support four measures providing "a foundation for a government truly republican." Three of these measures—abolition of primogeniture, abolition of entail and separation of church and state—were enacted in the course of the next twenty-five years; but, the fourth, the establishment of free public schools, was less readily acceptable. Again, in Congress in 1783 Jefferson reported the plan for a decimal coinage and drafted a proposed ordinance for the Northwest Territory. As ambassador to France from 1784 to 1789 he acquired a first hand knowledge of European society and witnessed the beginnings of the French Revolution. As secretary of state during Washington's first administration he supported Hamilton's funding and assumption plan on condition that the capital be located on the Potomac; but he was generally opposed to Hamilton's upper class, strong government program. Whereas Hamilton "feared most the ignorance of the people," his inveterate opponent was apprehensive above all of "the selfishness of rulers independent of them." During his two terms as president from 1801 to 1809 Jefferson reduced the forms of office to a "republican simplicity," endeavored to pay off the public debt, purchased Louisiana territory from France and in order to avoid war resorted to commercial embargo against France and Great Britain. From 1809 until his death in 1826 he lived in retirement at Monticello, advising his successors,

Madison and Monroe, founding the University of Virginia, occupying himself almost incessantly in study and writing and managing his estate—not successfully, since he died impoverished. He chose his own epitaph: "Here was buried Thomas Jefferson, author of the Declaration of American Independence, of the statute of Virginia for religious freedom, and father of the University of Virginia."

Next to Franklin, Jefferson was the ablest representative of the eighteenth century philosophy of enlightenment. Apart from inherited temperament three influences shaped his ideas. The first was environmental. Born and bred a gentleman farmer and possessed of a fine estate, he disliked urban life and activities; and living in the relatively democratic "up-country" he shared his region's opposition to the more sophisticated tidewater aristocracy. He thus represented a distinct class interest, that of the west against the east, of agricultural against industrial occupation. The second influence was philosophical. His natural predilections were rationalized in terms of the current philosophy, to which he was introduced in college by Dr. William Small, "from whose conversation I got my first view of the expansion of science, and of the system in which we are placed." Like most of the *philosophes*, he believed that God had created the universe according to an intelligible plan and that men had been given reason in order that they might harmonize their conduct and institutions with the "laws of nature and of nature's God." Accepting Locke's sensational psychology he believed that men were inclined to be good unless corrupted by ignorance and bad institutions. Happiest in the country, he regarded rural life as more "natural" than city life and agricultural pursuits as less "artificial" than banking and shopkeeping. His ideal society was essentially present in miniature before his eyes at Monticello. With a few changes it could be made, in keeping with his antislavery principles, into a community of free farmers economically self-sufficing or nearly so, sufficiently enlightened by free schools and governing themselves under the leadership of a benevolent country gentry through democratic-republican institutions; the powers of government distributed among township, county, state and national authorities would diminish in proportion to the territorial remoteness of the authority from the individuals concerned. The third shaping influence was his residence abroad, which confirmed him in the conviction that tyranny and privilege resulted

from an unproductive class battenning on the producers; and while this strengthened his belief in the superiority of a simple agricultural society under republican forms it raised some doubts as to whether the happier state of America was more than a special and temporary condition which would disappear with the disappearance of free land. Jefferson had no naïve, doctrinaire faith in republican institutions as a universal panacea. At best republican government "is the only form . . . which is not eternally at open or secret war with the rights of mankind." Yet experience seemed to show that "even under the best of forms, those entrusted with power have, in time, and by slow operations, perverted it into tyranny." Hence it was that "the tree of liberty must be refreshed from time to time by the blood of patriots and tyrants." Not any form of government alone, but the best form plus eternal vigilance, was the price of liberty.

Jefferson's philosophy was of the eighteenth century, his specific program suited to a simple agricultural society. Neither his philosophy nor his program is suited to the present industrial technological age. What has been of persistent influence and is still of value is his attitude of mind: his sympathetic acceptance of man as he is, his conviction that man can somehow master his environment to good ends, his assumption that human conduct and custom should be based upon the disinterested interpretation of the most exact and comprehensive knowledge attainable.

JEKELFALUSSY, JOZSEF (1849-1901), Hungarian statistician. Jekelfalussy studied law, economics and statistics at the University of Budapest and entered the Bureau of Statistics in 1871, the year in which it became an independent department. Working under Keleti, Jekelfalussy soon attained a prominent place in Hungarian official statistics. He participated in the census of 1880, the first to use individual cards. He organized that of 1890, introducing many reforms, among them a method of collecting vocational statistics in industry which attracted considerable attention abroad. In 1892 he was appointed head of the bureau; he reorganized it and introduced important innovations in the method of compiling the statistics of foreign trade and of agriculture. The published reports on the latter proved of the greatest help in shaping subsequent agricultural policy. Jekelfalussy introduced the use of individual blanks in the compilation of statistics of crime and social unrest, reorganized educational statistics and instituted new branches of statistical inquiry. He was instrumental in the enactment of the bill of 1897 which provided for the compulsory collection of statistics, and which was of the greatest significance in the further development of official statistics in Hungary.

JELAČIĆ, COUNT JOSIP (1801-59), Croatian statesman. Jelačić was educated at the Theresianum, a school for the nobility in Vienna,

and became an officer in the Austrian army. In 1848 he was appointed Croatian ban and military commander and as such governed almost all the Croatian lands then under Austria-Hungary—Croatia, Slavonia, Dalmatia, Medjumurje and Fiume—a unification which greatly stimulated Croatian national consciousness.

Jelačić was a prominent figure in the Croatian renaissance and in the formation of the Yugoslav nation. His greatest achievement was to turn the conflict between the Magyars and the Austrian court to the advantage of Croatia at a time when the Croats were seriously threatened with the danger of Magyarization. There were Serbs in Croatia and even in Hungary who were in a similar position with regard to the Magyars, and Jelačić in agreement with the Serbian leaders started the joint struggle against them. By opposing the Magyars and maintaining Croatian loyalty to Austria Jelačić performed an important service for the distraught imperial government and as a result secured significant gains for the Croats and for the Serbs as well. Magyarization in Croatia and in Slavonia was checked; Croatian was introduced as the official language and the Croats were united under the rule of one man. All these factors helped create conditions favorable to the foundation of a Croatia independent to some extent of Hungary. The joint war carried on by the Croats and Serbs in 1848-49 against the Magyars strengthened their relations and pointed the way in the political and national struggle. During the period of Germanization which followed the defeat of the Hungarian revolutionists Jelačić succeeded in obtaining certain substantial advantages for the Croats, such as the independence of the Croatian church from Hungary in 1852.

JELLINEK, GEORG (1851-1911), German jurist. Jellinek, the son of the rabbi Adolf Jellinek, was born in Leipsic but in 1857 moved with his family to Vienna. He devoted himself to legal and philosophical studies in Vienna, Heidelberg and especially in Leipsic, where the influence of Wilhelm Windelband permanently fixed his *Weltanschauung* in the new Kantian spirit. After nearly two years of experience in the Austrian public service he attempted to embark upon an academic career, but despite his many important publications antisemitic opposition hindered his

preferment. He ultimately became professor at Heidelberg, where he continued his activity as teacher and scholar from 1891 to his death.

Georg Jellinek's great importance as a political theorist lies in his skill at comprehensive synthesis. In the period of positivistic narrowing of the scope of the science of public law inaugurated by Gerber and Laband he constantly strove to rest its dogmatic treatment upon the foundations of the history of ideas, philosophy, comparative law and finally sociology. The central problem for him was the relationship of the individual to the state. He developed particularly the conception of the autolimitation of the state. In his *System der subjektiven öffentlichen Rechte* (Freiburg 1892, 2nd ed. Tübingen 1905) he revived ideas of the rights of man, and in his internationally celebrated *Die Erklärung der Menschen- und Bürgerrechte* (Leipsic 1895, 4th ed. Munich 1927; tr. by M. Farrand, New York 1901) he sought to connect the ideas of the celebrated declaration with Anglo-Saxon experience rather than with Rousseau. He gave systematic and brilliant expression to the whole range of his ideas in his *Allgemeine Staatslehre* (Berlin 1900; ed. by W. Jellinek, Berlin 1914). In this classic of German political theory, which in translation has also strongly penetrated foreign scholarship, he attempted, although not always successfully, to combine the sociology of the state—until then entirely neglected by German jurists—with the science of public law. Jellinek's intellectual universality as well as his political tact always restrained him from employing to an excessive degree in problems of political theory the method of jurisprudence developed from the private law.

JENKIN, HENRY CHARLES FLEEMING (1833-85), English economist and engineer. Jenkin was professor of engineering at the University of Edinburgh. His importance in economics rests on his contribution to mathematical economic analysis contained in a number of articles. In his first paper, "Trade-Unions: How Far Legitimate" (1868), his refutation of the economic opinion that unions could not raise wages anticipated Thornton's attack upon the wages fund doctrine and led him to a brilliant statement of the laws of supply and demand. The expression was algebraic in the form $D = f(A + 1/x)$, $S = F(B + x)$, where x is price and A and B are constants representing the dependence of demand and supply upon the states of mind of buyers and sellers respectively. This statement was elaborated and supplemented by diagrammatic analysis in his "Graphic Representation of the Laws of Supply and Demand and Their Application to Labour" (1870), in which he laid down three propositions or laws of demand and supply. Distinctions were made between the determination of price at a given time and in the long run, between changes in portions of the demand and supply curves near the market price and in the whole curves and between different conditions of changing cost of production. In a subsequent paper "On the Principles Which Regulate the Incidence of Taxes" (1871-72) he asserted his preference for the diagrammatic analysis, because the curve for a given good might be determined experimentally, while the algebraic function is likely to be complicated. This article, keen throughout, is most notable for its concepts of producers' and consumers' surpluses as a direct deduction from his theory of demand and supply. Here he prefers his own analysis to that of Jevons because the latter is in terms of utility which "admits of no practical measurement," while "statistics gathered through a few years would show approximately the steepness of each curve near the market price, and this is the most important information."

REDVERS OPIE

Important works: The second volume of Jenkin's *Papers, Literary, Scientific . . .*, ed. by S. Colvin and J. A. Ewing, 2 vols. (London 1887) and reprinted by the London School of Economics and Political Science, Series of Reprints of Scarce Tracts, no. 9 (London 1931) is a collection of his economic articles.

JENKINS, SIR LEOLINE (1623-85), English admiralty judge, civilian lawyer and diplomat. Jenkins fought as a royalist in the civil war and

upon the failure of the king's cause retired to his native Wales with Archbishop Frewen and Sheldon, later archbishop of Canterbury. There he formed the connections which laid the foundation of his subsequent advancement. He was later admitted to the College of Advocates of Doctors' Commons and about 1665 was made judge of the Admiralty Court; from 1676 to 1679 he was one of the English representatives at the Congress of Nijmegen. He became secretary of state in 1680 and resigned in 1684.

He achieved eminence in the fields of admiralty jurisdiction and international law. The agreements as to the jurisdiction of the Admiralty which were made in 1575 and in 1632 were not kept; the question was still open in Jenkin's day, for in 1661 and again in 1669-70 bills were introduced in the House of Lords to enact in substance the agreement of 1632. Jenkins argued unsuccessfully but with historical truth in their favor, pointing out that the common law courts were ignorant of the maritime and civil laws and could not take jurisdiction of many types of admiralty causes. Had the bills passed there can be little doubt that the law merchant would have developed in England and in America in the admiralty courts.

Jenkins' most enduring work is to be found in the Statute of Frauds [29 Car. II, c. 3, sect. 17 (1677)] and in the Statute of Distributions regulating the intestate succession of personal property [22-23 Car. II, c. 10 (1670)]; he was the principal author of both these statutes, which are still substantially in force in every common law jurisdiction.

D., "The Original Drafts of the Statute of Frauds and Their Authors" in *University of Pennsylvania Law Review*, vol. lxi (1912-13) 283-316.

JENKINSON, CHARLES. *See* LIVERPOOL, FIRST EARL OF.

JENNER, EDWARD (1749-1823), English physician. Jenner was born at Berkeley, Gloucestershire. After studying medicine under the surgeon Daniel Ludlow and under John Hunter he obtained the degree of doctor of medicine from St. Andrews, Scotland, in 1792. He per-

formed his historic experiment with cowpox inoculation on the eight-year old James Phipps in 1796 and in 1798 published the findings of twenty-three cases in *An Inquiry into the Causes and Effects of Variolae Vaccinae* (London 1798, 3rd ed. 1801).

Contrary to the widely prevalent belief, Jenner did not discover the principle of immunization by inoculation. Variolation, inoculation of the smallpox germ for purposes of immunization, had been widely practised in Europe and America throughout the eighteenth century and had reached a high degree of success in the hands of specialists. Vaccination offered a less dangerous and simpler procedure than did variolation, and Jenner's careful instructions as to how to perform cowpox inoculation were invaluable contributions to medical science. But Jenner's role in the promotion of vaccination has been exaggerated largely through John Baron's partisan biography. Not only had the principle that cowpox offered immunity to smallpox been known prior to Jenner's work and vaccination previously been performed, but the credit for convincing the medical profession of the efficacy of the practise by sufficient evidence belongs to George Pearson and William Woodville rather than to Jenner. Pearson and Woodville were also the first to establish an organization for free vaccination and for the distribution of vaccine matter. They acknowledged the need for revaccination, which Jenner persistently denied.

JESSEL, SIR GEORGE (1824-83), English judge. Jessel, who was master of the rolls, may justly claim an honorable seat at the symposium of the masters of English equity. Posterity in naming him in the same category as Nottingham and Hardwicke would be according him no more than his achievements merit. In a sense also he may be said to have stood in relation to the modern understanding of equity in much the same position as Marshall stood in relation to the interpretation of the United States constitution, in that the life work of both was destined to fall on the morrow of great events, events which demanded for the fruition of their purposes exponents of strength and genius. Without Marshall the United States constitution might

today be but a rigid and didactic decalogue; without Jessel the Judicature Acts might have been interpreted in such a way as to bring chaos into the jurisprudence of English courts.

Two great decisions of Jessel, by showing clearly that the Judicature Acts effected primarily an alteration in adjective not in substantive law, have hewn down before it could have time to grow to any stature the forest in which many a modern jurist might have lost his way. In *re Hallett's Estate* Jessel pointed out the fundamental differences in history between law and equity and described the different machinery which each can provide for the recovery of money. In *Walsh v. Lonsdale* an even more difficult question arose: did the Judicature Acts abolish the difference between a lease and an agreement for a lease? Jessel resisted the temptation of simplicity and concluded that the effect of the acts was not thus drastic. He discriminated and held only that an agreement for a lease which equity would specifically enforce would be regarded as a lease for the purpose of giving effect to all its terms, although those terms might have been such as law would not countenance. His decision in *Pooley v. Driver* is a landmark in the law of partnership. It is the converse of *Cox v. Hickman*, the great case which laid down that profit sharing does not by itself necessarily constitute the partnership relation. Jessel's cases have been digested by A. P. Peter under the title *Analysis and Digest of the Decisions of Sir George Jessel, with Full Notes, References and Comments* (London 1883).

H. G. HANBURY

JESUITS. When in 1534 Ignatius Loyola organized a small band of students at Paris, his intention was to create an order for missionary service in Palestine. Had this been realized, the society would never have acquired its historic significance. But the revival of war between Venice and Turkey prevented travel to the Orient, and in 1537 Loyola went to Rome in quest of a substitute for his frustrated purpose. There he formulated a new program which included in addition to missionary work educational activity, preaching and the service of the papacy. The society immediately entered upon active pursuit of these objects, but its definitive character was not shaped until it emerged as the most militant weapon of Catholicism against Protestantism.

The essential ethos of the Jesuit order is to be understood only in the light of the reaction produced in the Catholic church by the disruptive consequences of the Protestant revolt. At the time of Loyola's arrival in Italy the Reformation had gained sympathizers even at Rome, and the papacy under Paul III (1534-49) had responded to the menace by stiffening itself against all compromise with innovation. Fused with the religious fervor and militant passion which Loyola brought to Rome this spirit molded the Society of Jesus, giving to the church the instrument for aggressive warfare unprovided by its older institutions. The whole future policy of the order was determined by the undivided purpose of annihilating the enemies of the church. The Jesuits became pledged to crush all manifestations of nonconformism within Catholicism with the same ruthlessness as open secession, for the exigencies of warfare demanded unquestioned unity of both doctrine and guidance. The slightest concession might threaten the whole structure. The immutable, absolute authority which they needed they ascribed to the church by identifying the ecclesiastical with the divine. The church in its historical form became for them the visible realization of God's will; it was to be *semper eadem*; its dogmas like its constitution and ritual were unimpeachable. Having evolved such a conception of the church the Jesuits found in it ample justification for any means they might employ to preserve it against the inroads of change. Their aim constituted an injunction to intellectual rigidity and to obduracy against pity. The Jesuits may be compared with the mendicant orders which had risen and been used by the church against the less serious heresies of the thirteenth century. The Dominican order had been inclined to favor the Inquisition and the application of other violent methods against apostates, but in the long run it had been more concerned with science and the salvation of souls within the faith. The Jesuits, on the other hand, have never as an order relaxed the spirit of inexorable militancy in which it was conceived, although individual exceptions have sometimes appeared among their members.

The Jesuits represent the final stage in the evolution of religious orders away from the solitude and fixity of monasticism. With the mendicant orders or friars the glorification of flight from the world which had been characteristic of the Benedictines, Cistercians and Premonstratensians had been supplanted by the ideal of

service through contact with the laity. To fit their purpose they had developed an institution allowing peregrination but still sufficiently influenced by monasticism so that communal life, the obligatory monkish garb and the common choral prayer were retained. All these elements were discarded by the Jesuits as obstructions to active work in an agitated world. They became "clerks regular" in contrast to both friars and monks.

The Society of Jesus was definitely organized in 1539, when Loyola drew up a preliminary code of laws which was confirmed the following year by the bull *Regimini militantis ecclesiae*; its definitive constitution, based on the cumulative experience of the founder and his associates, appeared in its final form in 1558. These documents are the institutional expression of the reaction of Catholicism to its precarious status about the middle of the sixteenth century. Virtually all power was placed in the hands of the general of the order, who was chosen for life. Without abandoning the semblance of representative government, introduced by the friars simultaneously with their development of a centralized direction of all branches of the order in place of the older system of autonomous monasteries, the Jesuits rendered such a check upon administrative efficiency innocuous. The General Congregation, closely corresponding to the General Chapter of the mendicant orders, although it possessed the sole right to legislate, to elect a new general and to impeach an unworthy incumbent met, except in extraordinary circumstances, only after the general's death. The type of organization and nature of the society were thoroughly harmonious with the founder's Spanish heritage. Loyola had before his eyes the ideal of a holy militia, of a military Company of Jesus, as was natural for a Spanish nobleman whose countrymen and class had for centuries engaged in fanatical crusades against the Moors. The society in fact drew its most zealous adherents from Spain; and nowhere was it to achieve wider extent.

Obedience occupied the position held by renunciation among the Benedictines. It was Loyola's intention to derive the motive power of the order from the pure love of God, but as an inevitable consequence of the dogmatic and anthropomorphic nature of the Jesuit conception of God the emphasis was transferred to blind acceptance of the views espoused by the order. The idea that the dissenter was not only misled but reprobate was exalted by the Jesuits into an

infallible principle. While from the time of the military orders there had been a progressive tendency on the part of religious orders to stress obedience, no other order, not even the Franciscans, whose founder had imposed a kind of "corpse-like" submission, exacted such complete prostration of its members before the order's dictates. The individual Jesuit was regarded as a robot in the hands of his superiors. With a view to recruiting only persons of sufficient talent and strength to extinguish their own wills requirements for admission to the society were made more stringent than in any other order and a long period of probation was enforced.

The peculiar Jesuit device for generating a corporate spirit was the Spiritual Exercises—a regimen of intensive mental, physical and religious drill which is prescribed in detail in Loyola's *Exercitia spiritualia*. Begun probably in the 1520's and finally approved by Paul III in 1548, the exercises reflect at the same time Loyola's military experiences and the agonized course of self-immolation which had led him to the final victory of unreserved surrender. Twice during his lifetime each member of the order had to undergo the complete drill, which might extend over a period of several weeks; and every year he had to undergo an abridged form. Except for the presence of a master of exercises to supervise the performance and within certain clearly defined limits to adapt the rules to the special weaknesses of the individual absolute solitude was required. According to a carefully graduated system the practitioner rose through meditation, self-examination and purgation from all earthly concerns to the final ecstatic union with God. The drill shows a minute knowledge of the interaction between physical and psychological states; no stimulus was neglected which might goad the pupil's imagination to the point where the teachings of the church and of the order become identified with divine truth. All theological speculation was rigidly excluded; the desired goal was attained by stirring the depths of the pupil's soul and causing him not to analyze but to visualize the mysteries of the Catholic religion. By thus using the practises of ascetics and saints as a means rather than an end Loyola evolved an unfailing technique for inspiring the members of the order with a superpersonal ideal, which complemented the discipline involved in constant struggle with the enemies of the church.

Although the original bull of confirmation in 1540 limited the membership to sixty, the volume of applications for admission made it necessary

to repeal this rule within three years. By 1555 the order numbered approximately one thousand members. From the outset it engaged in preaching, in educational work in both Catholic and Protestant countries and in home missionary work of all kinds. Within the first decade of its existence it organized extensive foreign missions: when Francis Xavier, one of the original members, died in 1552 he had founded Jesuit missions in the East Indies, India and Japan and converted thousands to the faith. As the order's conflict with Protestantism became more clearly defined, its lines of activity multiplied; and while throughout its history it never removed emphasis from its original aims it began its characteristic practise of penetrating into the world by any avenue that promised success. The Jesuits insinuated themselves into the confidence of princes, became the confessors of royalty, diplomats, noted organizers. The convent was not the fixed home of the Jesuit but merely a meeting place visited by a transient, who was assigned by the order to whatever post he could fill most effectively. Since in view of the political complexion of the age the most practical way of achieving submission to the church was through influencing kings and nobles, the order came to favor the selection of members from men of the world and of social position. The society itself trained its recruits to have the adroitness of courtiers, the cleverness of diplomats and a profound knowledge of human nature. The type of Jesuit stood out in sharp contrast to the religious of the older orders.

By 1550 the West was covered with a network of Jesuit institutions and establishments. At Loyola's death in 1556 it organized its various branches into twelve provinces, one of which was Indo-Japan, one Brazil and one Ethiopia. The others were Portugal, Castile, Aragon, Andalusia, Italy, Sicily, upper Germany, lower Germany and France.

Through their preaching and instruction the Jesuits were more than any other factor responsible for the regeneration of Catholic consciousness which set in throughout Catholic Europe about the middle of the sixteenth century. They founded seminaries for the education of priests, whose ignorance and unfitness had been an important cause of the decadence of the church. Jesuit schools for the laity mushrooming throughout Italy, Spain and Portugal imbued the rising generation of Catholics with the Jesuit faith and ideas. The great Collegium Romanum, which Loyola opened in 1551, became the

model for all Jesuit educational institutions. Although with progressive intensity they concentrated their attention upon the youth of the upper classes they also won much sympathy during the early years by establishing orphanages and industrial schools for poor children. Their influence upon the policies of the church became particularly apparent at the last session (1562-63) of the Council of Trent, which built enormously upon two decades of Jesuit experience. It was chiefly as a result of their activity and especially of the counsel of Diego Láinez, one of the first and most important of Loyola's followers and general of the order from 1558 to 1565, that this session abjured all doctrinal compromise with the reformers and strengthened the influence of the pope in the church. The council, however, stopped considerably short of the Jesuit position that the dogma could be preserved only if the pope were given absolute authority in church matters and over councils. From the middle of the sixteenth century until the nineteenth, when they finally carried the doctrine of papal infallibility through the Vatican Council of 1870, the Jesuits persisted in their espousal of papal monarchism, seeking to apply to the government of the church the principles of their own government, which has been rightly characterized as an absolute monarchy. For this reason and in return for the order's unabated devotion to their service the popes with a few exceptions requited it with their protection and favor; customarily it was the dominant power at the Holy See.

However important might be the internal reform of Catholicism, the essential task of the Jesuits was the elimination of Protestantism in its own strongholds. The first Jesuits arrived in Germany, the most threatening terrain, during the 1540's. That in 1543 they gained the adherence of Petrus Canisius (1521-97) was of utmost importance for their success on German soil. Canisius, whose rich correspondence mirrors half a century of incessant activity, became the soul of the German movement, the founder of numerous colleges, the author of a most effective catechism and the first provincial general for upper Germany and Austria. Here even more systematically than in countries less infected by heresy the Jesuits followed a definite plan of campaign. Their first objective was the erection of colleges as a base for all future operations. After winning the young they penetrated into family life through their pupils as well as through lay religious societies, which they

founded everywhere in great profusion. At the same time they carried on an offensive through the courts. In 1552 a Jesuit college was established at Vienna, in 1556 at Prague, in 1557 at Cologne, in 1559 at Munich. Soon Augsburg, Dillingen, Treves, Mainz, Speyer, Würzburg, Halle, Fribourg in Switzerland as well as many other cities had flourishing Jesuit colleges. The Vienna institution included 400 pupils within three years, that at Cologne 480 within two years.

As systematized by General Aquaviva (1543-1615) in the *Ratio studiorum* (1585-99), a famous document in the history of pedagogy, the Jesuit plan of education represents the most thoroughgoing attempt ever made on a large scale to inculcate devotion to church ideals through lay instruction. Religious education was the fundamental element in the structure. But the fame and tremendous patronage of their schools depended to a large extent upon the emphasis which they attached also to the study of the classics. While they relentlessly expurgated the objectionable or dangerous, this limitation was offset by the pedagogical skill of the professors, who were rigorously trained in their own institutions, and by the solidity of instruction which they imparted to their pupils. In general the atmosphere of their schools was far from ascetic or austere; and in this respect they presented a sharp contrast to many of the Protestant schools, where plain living was interpreted in a rigid sense. Individual peculiarities became an object of intense concern to the teachers. Their goal was to ferret out the special aptitudes of the pupil, to break his resistance, to link him indissolubly to the order and to utilize the best available material for their own ends. They made overtures to self-love and the spirit of emulation: at frequent intervals the pupils participated in public declamations and disputations, competed for prizes, exhibited their work in the classics and in other fields and staged dramatic performances. In addition to stimulating and entertaining the pupils this served the purpose of impressing and influencing the outside world. Since the Jesuits offered free tuition they were able to attract the talented children of impecunious parents; the same consideration often impelled Protestants to entrust them with their children. During the first century the order developed into a teaching corporation of unprecedented influence and extent. In 1640 it had 521 colleges: 116 in Italy, 104 in the Iberian peninsula, 83 in Germany, 79 in France, 39 in the Low Countries and 30 in

Poland. It undertook elementary instruction only with reluctance and particularly in those regions where Protestantism was most rampant it catered almost entirely to the upper classes, for the future was to be won through the youth of the élite; in most of the European capitals and metropolitan centers there were special Jesuit colleges for children of noble birth. The majority of the Jesuit educational institutions were either colleges corresponding to the French *lycée* and the German *Gymnasium* and offering chiefly classics or institutions of higher learning, including philosophical and theological academies and universities (*Studium generale*). In addition to their own academies and universities the Jesuits acquired innumerable chairs in older institutions. In the middle of the seventeenth century higher education in Catholic Germany, the Spanish Netherlands, Hungary, Spain, France, Italy, Portugal and Poland was largely vested in the Society of Jesus. The Jesuits also founded and operated a great number of seminaries, which supplied the churches of all Europe with a highly educated and cultured secular clergy.

The Counter-Reformation was in large measure the work of force, and without the assistance of state power the success of the Jesuits would have been greatly diminished. Soon perceiving on their side the indispensability of the order in the battle against Protestantism the Catholic governments in the two chief battlegrounds, Austria and Bavaria, as well as in the German ecclesiastical principalities accorded it every mark of royal favor: they showered it with endowments, assisted it in founding colleges and procured for its members university appointments. At the Catholic courts the Jesuits acquired impregnable positions as confessors, an office which sometimes made them along with the academicians the most influential councilors in the realm. Not satisfied with the hold that the confessional gave them over the princes and the female members of the royal families the Jesuits attempted, wherever possible and by recourse to whatever intrigue the situation required, to gain mastery of the lay advisers of the governments.

Within a short time either by persecution or by less violent methods the Catholic church was reestablished in Bavaria, Austria and the Rhineland. Where not annihilated the Protestants in these regions were forced into a defensive position at the mercy of the princes, whose promises to them were never kept when the Jesuits were court advisers. The order relaxed its efforts in Germany only when the Thirty Years' War ter-

minated Protestantism in Austria and Bohemia. The same methods were employed in France, leading eventually to the virtual extinction of French Protestantism: undoubtedly the order had its share in the Massacre of St. Bartholomew. It conducted a fervid campaign in the Low Countries and Switzerland as well as in Poland, Lithuania, Hungary, Transylvania and even in purely Protestant countries. It was chiefly instrumental in converting the daughter of Gustavus Adolphus, Queen Christine of Sweden, although before she had taken the first step public resentment compelled her to abdicate. It won Augustus the Strong of Saxony to the faith, as it did Winckelmann. For a time it nurtured hopes of regaining Russia. England, to which it sent its first mission in 1580, was the field of desperate efforts in the face of a persecuting government; its hopes were renewed with the accession of Charles II only to be finally blasted with the ousting of his son James. But wherever Catholic government held sway and in some Protestant regions the Jesuits were completely successful. If the states supplied the power, the strategy and direction as well as the inspiration came from the order. In Germany, Switzerland, France and the Low Countries the Counter-Reformation was in fact chiefly the work of the Jesuits.

Home missions for religious revival and for social work, preaching and disputations for the benefit of the learned went hand in hand with court intrigue and education, although the latter function always absorbed the energies of the majority of the order. To heighten the aesthetic appeal of the church ritual the Jesuits used every means that an age of baroque art and absolutistic government could provide: magnificent churches, paintings and statues of enraptured saints, altars overflowing with gold, dazzling clerical robes, incense and intoxicating music. The princes, eager to see their personal majesty reflected in superbly wrought courts and churches, found them indispensable advisers in matters of art, while the masses became aware of the pitiful contrast between Catholic splendor and the starkness of Protestantism with its bare churches and simple services. Thus under the leadership of the Jesuits a new church was created—a church which in Germany at least was more sumptuous, more inflexible, more propagandistic, more fanatical but at the same time purer and more spiritualized than any hitherto in existence.

The Jesuits also fortified the church with a vast arsenal of apologetics and anti-Protestant literature. With the assistance of papal favor it

soon tended to achieve a monopoly of Catholic theology, its approach to which was determined by the orthodox scholasticism of the thirteenth century. Until the present day the Jesuits have consistently remained advocates of Thomism. Among the numerous distinguished theologians whom they educated were Gregory of Valencia (1550?-1603), Bellarmine (1542-1621) and Suarez (1548-1617). While it was in the theological sphere that they achieved particular eminence in institutions of higher learning they also directed their scientific and literary energies into diverse other channels. Just as through their vast output of pedagogical treatises and textbooks they made possible that complete unity of instruction from which emanated the chief strength of their school system, so they sought to infuse the Jesuit spirit into all branches of higher education. Historiography owes to them the *Acta sanctorum* (begun in 1643) besides extensive collections on the history of the councils and innumerable shorter works. They produced many eminent natural scientists, particularly physicists and astronomers. Wherever Jesuit missionaries came in contact with foreign peoples they turned to the study of ethnology. In *Letters édifiantes* and other productions they have left invaluable documents on Asia Minor, Tibet, India and Central and South America. The annual reports, or *Relations*, letters, journals and other records of their American missionaries (collected as *The Jesuit Relations and Allied Documents . . . 1610-1701*, ed. by Reuben G. Thwaites, 73 vols., Cleveland 1896-1901) provide the sole available source of information on many aspects of the life of the prehistoric American native.

The period of the apogee and glory of the order was the first century of its existence. Although its militant spirit did not wane, after the Thirty Years' War its activity was greatly restricted in Protestant countries. Moreover, as a liberal and tolerant temper became injected into Catholic circles under the influence of the Enlightenment, the success of the Jesuits declined proportionally in those regions where they had formerly been supreme. Their hold over Catholic countries had already slackened when as an aftermath of their hegemony they won a twofold victory in France: the revocation of the Edict of Nantes in 1685, which to a considerable extent was the result of their influence upon Louis XIV; and the destruction of Jansenism, which was entirely their work. Between the Jansenists, adherents of a pietistic movement drawing its inspiration from a reversion to the ideals of primi-

tive Christianity, and the Jesuits a literary controversy had raged since 1643 on the question of communion and penance. In 1656 Blaise Pascal entered the fray with his celebrated *Lettres provinciales*, a mordant satire on the moral and political views of the Jesuits. The Jesuits were able through their superior position at the court to obtain the burning of Pascal's book in 1660 and in 1713 the bull *Unigenitus*, which outlawed the whole Jansenist movement. But Pascal's condemned ideas continued to exert pressure. In the seventeenth century as in the nineteenth the Jesuits saw many of their pupils develop into outspoken enemies: Galileo, Descartes, Bacon, Taine and Hoensbroech are only prominent examples.

After curtailing the influence of the order the Enlightenment finally led to its suppression. The rationalist spirit although nowhere attaining the same potency as in France penetrated even Spain and Portugal; in the second half of the eighteenth century there were important ministers in almost every European government—Aranda, Pombal, Choiseul, Tanucci, Kaunitz—who were more or less swayed by the ideas of the *philosophes*. In 1759 the Jesuits were expelled from Portugal; in 1764, two years after the Parlement of Paris had decreed the suppression of all Jesuit colleges, the order itself was dissolved in France; in 1767 Spain and Naples banished it; and the following year Parma followed their example. These governments jointly importuned the pope to take the ultimate step of abolishing the order in its entirety and in 1773 Pope Clement XIV fulfilled their request with the bull *Dominus ac redemptor noster*. In all probability Clement's action was a reluctant surrender to overwhelming pressure. He justified it on the grounds that the Jesuits menaced the peace of the church by their conflicts among themselves, with the secular clergy, with other orders and with the princes. The friction necessarily created by the nature and methods of the Society of Jesus is in fact the explanation for the circumstance that the Catholic governments in the eighteenth century joined the Protestants in hostility to the order and that the demand for its dissolution emanated from Catholic quarters. A strong popular sentiment supported this demand. The age of the Enlightenment, it is true, looked with disfavor upon the whole system of Catholic orders, regarding the enormous expansion of the convents and the not uncommon idleness of their inmates as an affront to "reason." But the Jesuits had given more grievous

and more urgent causes for complaint, which account for their suppression while the other orders survived.

Prominent among these causes was the intolerance of the Jesuit outlook and the basic inflexibility of their educational system—an inflexibility which gravely threatened the continued existence of the disintegrating Catholic church. Until their suppression the Jesuit colleges still surpassed all other Catholic schools. But the spirit of the age demanded compromise with the principles of "reason." No criticism impelled the Jesuits to transcend confessional limits or to modify the compound of religious propagandism and humanism which they had created for all time in the sixteenth century.

A serious source of friction was provided by Jesuit influence in affairs of state. This influence had at times, particularly in Spain, Portugal and the Italian states, amounted almost to omnipotence not only in matters of religious policy but in the secular concerns of governments; in addition to its constant entrée into royal circles through confessorships and court tutorships the order had had representatives, like Father Nidhart in Spain, Father Fernandez in Portugal, Father Lachaise in France, Father Vota in Poland and Russia, in official diplomatic and ministerial posts. But even at its apogee the political status of the order had never been safe from intermittent strictures and sometimes from more violent reaction. Charles V and Philip II always viewed it with distrust. From 1594 until 1604 the order was banished from France after its holdings had been confiscated. In 1606 the Republic of Venice expelled it for fifty years. In the eighteenth century, although Jesuit confessors still held stoutly fortified positions in most royal families, the policy of the Catholic governments toward them had tended to a constantly growing extent to turn upon political considerations. One force with which the order collided was national particularism, naturally skeptical of these potentates who not only were servants of a foreign general but were themselves frequently foreigners in the countries which they served. Although the order officially prohibited such activity, they could on innumerable occasions be plausibly accused of unsolicited and inopportune meddling and of intrigues that did not stop at spying out state secrets. Numerous works were written, especially in Gallican France, to demonstrate that Jesuit doctrines were dangerous to the state. Whatever justification for antiregalism was offered by individual Jesuits like Mariana,

Suarez and Bellarmine, it can hardly be proved that they countenanced tyrannicide on principle or that they had a part in the murder of Henry IV of France. Popular imagination has shown little reserve in its imputations against the Jesuits.

The wealth of the society is for the most part matter of legend; the Jesuits themselves preserved a discreet silence with regard to their financial affairs. Undoubtedly a great part of their income was required for the maintenance of their institutions; and much of what appeared to be opulence was the result of efficient administration. To a large extent their income was derived from endowments, from the estates which their members were required to transfer to the order after entrance and from the operation of their other holdings; but this amount was supplemented by vast commercial enterprises, such as the lucrative colonial trade carried on by the Jesuit missions in India, in Mexico, in the Antilles and in Brazil. If critics of the order disapproved of its participation in trade, they were still more scandalized at its banking and speculative activities; that Father Lavalette, whose bankruptcy cost his creditors over 2,000,000 livres, had acted like many other Jesuit speculators without the consent of his superiors did not save the order from a renewed outburst of popular resentment, which culminated in its dissolution in France. Besides helping to alienate public opinion and creating a temptation for the confiscatory impulses of princes the Jesuits' wealth aroused the jealousy of other orders and of the secular clergy. The attitude of the latter, which was to some extent responsible for the dissolution, must be explained in part by envy not only of the wealth of the Jesuits but of their privileges and exemptions, of their influence in high circles and in general of their overshadowing power. It must be remembered that in 1759 the order still had 22,589 members in 41 provinces, 609 colleges, 171 seminaries and 270 missions.

But other motives were operative in the continuous attacks leveled against the Jesuits by sections of the church from the time of the Dominican Cano (1509-60) until and following Pascal. The doctrine of grace formulated by the Jesuit Molina in 1588 was combated with particular violence. The order was often accused of giving unconditional support to the views of its members. Its identification of itself with the divine church—this position is clearly expressed by the great general Aquaviva—and the inferences it drew as to its own infallibility were

flailed by Catholic theologians as sophistical and even heretical. Certain generals could be pointed to who had disregarded the views of the pope on controversial doctrines and made their own pronouncements binding upon the order. In spite of all efforts to secure cohesion, including the system of espionage, which it employed with such elaborate finesse among its members as well as in its relations with the laity, the order no longer presented a united front against its enemies in the eighteenth century: internal dissensions hastened its end.

Irrespective of the criticisms urged by the church it cannot be denied that the Jesuits were often led by anticipation of victory to carry to excessive lengths their policy of adaptation to the world. To win the masses they suffused religion with sensuousness. Their missionaries transmuted it into a superstitious cult. While not universally approved by their members their characteristic ethical values represented the perfection of casuistry; equivocation, mental reservations, the doctrine of probabilism, according to which an act could be assumed to be legitimate if it was not known to be prohibited, were resorted to and condoned to provide the necessary latitude for their activity. As proselytizers among the Protestants they shunned no machination however clandestine to attain their goals; families were disrupted, children alienated from parents and wives from husbands. Such methods might be justified by the order on the premise that the supreme crime was heresy, but they helped to rob it of the popular confidence which was one of the necessary means to its ends.

If the scientific contributions of their missionaries be left out of consideration, the permanent results of their work outside Europe were not proportional to the extraordinary zeal manifested. In Japan, China and Korea at least they made serious blunders; in Japan, for instance, political entanglements resulting from their activity have been held responsible for a large part of the antipforeignism which led to the expulsion of all Christians in the seventeenth century. In the Philippines, the Marianas Islands and Central and South America they had more success. The famous Jesuit "state" of Paraguay, which the Jesuits organized under Spanish sovereignty and administered from 1609 until it was dissolved by the Spanish government in 1767, was a virtual autocracy controlling the native population by communistic economic and social regulations. To counterbalance the extravagant charges leveled against the Jesuit administrators

by their opponents the state has been praised as a communistic utopia, even by such enemies of Catholic orthodoxy as Voltaire, Diderot and Lessing. That the natives received good treatment from the Jesuits is beyond doubt. Complications between the state and Portugal and Spain were used by both governments as a convenient case against the Jesuits and became one of the important alleged causes for the dissolution of the order.

The cultural and political reaction after the Napoleonic era and the drift toward ultramontanism brought the immediate restoration of the order by the bull *Sollicitudo omnium ecclesiarum* of 1814. With the nucleus of several hundred adherents in England and in Russia, countries where the absence of papal authority had enabled the Jesuits to survive after the dissolution, the order became quickly reorganized in all countries. Bishops as well as the Catholic nobility helped to create for them new spheres of activity and provided them with abundant material resources so that they were able to recover from the confiscations which had accompanied the dissolution. Aristocratic converts in Denmark, for instance, gave them notable assistance. Where educational institutions were transferred to them, as occurred for a time in France, in Spain and in Portugal, they received state subsidies. The order itself established numerous new colleges in all parts of the world, even founding universities, as at Tokyo, and taking over theological faculties, as at the universities of Innsbruck and Louvain.

Without repudiating its original purpose in the slightest degree the order considerably modified its policies to fit the changed conditions. Usually it abstained from high politics and became resigned to the loss of the strongest prop of its early period, the Catholic court. But at the Curia it was supreme; it directed official theology and guided the rapid course of ultramontanism until that movement reached its logical conclusion in the decree of papal infallibility by the Vatican Council of 1870. It made itself the champion of conservative interests, which accounts for its popularity in aristocratic circles. But at the same time it promoted if it did not create "political Catholicism," the policy of utilizing parliamentarism and democracy for the furtherance of the church.

For the liberal bourgeoisie—the descendants of the eighteenth century enemies of the order—the Jesuits continued to typify Catholic obscurantism and intolerance, popery and authoritari-

anism. Wherever this class triumphed and not infrequently on other occasions they were banished: thus they were excluded from Spain in 1820, in 1835, in 1868 and in 1931; from Portugal in 1834; from Switzerland in 1847; from Russia in 1820; from France in 1880 and in 1901. Both the individual Italian states and after 1860 the Kingdom of Italy repeatedly expelled them. A reaction in favor of Catholicism, the vanishing of the Catholic phobia and sometimes the emergence of a radical menace might lead to their readmission or to the extension of privileges. France permitted them to return in 1914 for educational purposes; Germany lifted the ban, although leaving minor restrictions, in 1917. As soon as it was expelled from one country the order intensified its activities elsewhere. Exiled Jesuits have swollen the ranks of foreign missionaries. Many of them have migrated to Protestant countries; it is only in England, the United States, Denmark and Sweden that the order has been unmolested since its restoration.

In 1917 the order had about 17,000 members and was continuing to grow. Today its schools are united into a central system by their affiliation with the Collegium Romanum (or Università Gregoriana), which was reestablished in 1824. Preaching, home and foreign missions and nursing remain a constant part of the order's program. It takes a lively interest in all fields of scientific inquiry, occasionally giving to these investigations a highly modern appearance. In theology and in historiography the Jesuits are still the guardians of rigid orthodoxy; and within Catholicism they have in addition to enthusiastic supporters many adversaries who disapprove of their intolerance and intellectual bias. But the order continues to exercise a powerful influence through its energetic literary and polemical activity; through its magazines, the most important of which is *Civiltà cattolica* (1850-); and through its carefully selected and excellently trained members.

JEVONS, WILLIAM STANLEY (1835-82), English logician, economist and statistician. Jevons, the son of an iron merchant, was brought up in Liverpool and at the age of fifteen was sent to University College School, London. In 1851 he entered the University College, studying chemistry, mathematics, Greek and Latin. In the first he was a noteworthy student and in 1853 was offered the post of assayer to the newly established Royal Mint in Sydney, New South Wales, where he arrived a year later. In Sydney his spare time was first devoted to meteorology, but he was soon reading Adam Smith and the *Reports* of the Social Science Association. As his interest in human phenomena grew he read moral philosophy and carried out a social survey of Sydney, of which the manu-

script, but not the map which accompanied it, is extant.

He resigned in 1859 to return to University College and study logic and political economy. After touring the Australian gold fields he sailed by way of Peru and Panama to New York and traveled in the United States. He passed the M.A. examination in logic, philosophy and political economy in June, 1862; he had already been actively at work on statistics and had published two diagrams. These were followed by two papers read at the British Association for the Advancement of Science in 1862, which foreshadowed all his future work on the mathematical theory of economics and on the study of periodic commercial fluctuations. In 1863 he was appointed to Owens College, Manchester, as tutor, where he later became professor; he had just published his first important work, *A Serious Fall in the Value of Gold* (London 1863), which was followed by *Pure Logic* (London 1864) and *Elementary Lessons in Logic* (London 1870). His attention was next turned to the coal question and then to the further development of his mathematical theory of economics. After publishing *The Theory of Political Economy* (London 1871; 4th ed. by H. Stanley Jevons, 1911) he turned again to logic and wrote the *Principles of Science* (2 vols., London 1874; 2nd ed. 1877). In 1876 he resigned from Manchester, having accepted the chair of political economy at University College, London, but resigned in 1880 because of ill health and a desire to devote his whole time to writing books that he had planned, especially his *Principles of Economics* (ed. by Henry Higgs, London 1905). He was drowned in August, 1882, before the *Principles* was finished.

Jevons' writings fall into three main classes: papers giving the results of his investigations in natural science; books and papers on logic and moral philosophy; and books, pamphlets and articles on political economy and social reform. He gained reputation by writing *The Coal Question* (London 1865, 2nd ed. 1866), which led to the appointment of a royal commission to report on available coal reserves. His argument, which has been much misunderstood, was that although the actual exhaustion of its coal seams was a remote contingency Great Britain must suffer at no distant date from the increased cost of mining coal at great depths and from the competition of coal, iron and steel industries in Europe and America, assisted in their growth by vast reserves of coal which could be cheaply mined.

Jevons' studies of the science of logic, in which he was much engaged during the years he spent at Manchester, developed on lines parallel with his work in mathematical economics. Jevons followed Boole in his mathematical analysis of logic but simplified many of Boole's methods. He developed his theory of logic as an exact science and his conception of scientific method at greatest length in the *Principles of Science*, a book which is still of great interest to mathematicians and logicians.

His economic works which are now best known relate to economic theory, fluctuations of prices (with index numbers), the causes of commercial crises, and money and banking. At a time when English thought was dominated by John Stuart Mill's exposition of economics Jevons developed the theory of utility, distinguishing final degree of utility (i.e. marginal utility) from total utility, applying the conceptions and symbols of calculus, which led to the equation of exchange, and thus laid the foundation on which economic theory was elaborated by later English writers. Although he was ignorant of the fact, his method had been anticipated by Gossen; it was simultaneously but independently discovered by Walras and was very similar to that of the Austrian school (Menger and Wieser). Jevons declared that value rested on utility, not on cost of production as taught by Mill. Although he overemphasized demand as determining price, careful reading shows that he by no means ignored the effect of the supply of the factors of production.

His well known index numbers of prices were first calculated for the period from 1845 to 1862 and later extended back to 1782 (*Investigations in Currency and Finance*, ed. by Herbert S. Foxwell, London 1884; new ed. 1909). His statistical work on periodic fluctuations in the money market served as a model for later investigators; but his theory of the periodicity of commercial crises has been misrepresented. He did not suggest that sun spots were the cause of crises but pointed out that the periods of sun spots and crises, also those of famines in India, corresponded closely, and that it was reasonable to suppose that variations of solar radiation would affect harvests in tropical and semitropical regions and thus the demand for British goods. His *Money and the Mechanism of Exchange* (London 1875) was frequently reprinted and translated.

In his writings on general and social economics Jevons took the utilitarian standpoint; he was

an uncompromising free trader and a disbeliever in the efficacy of trade unionism to raise wages. He favored cooperation and schemes of workers' copartnership.

JEWISH AUTONOMY in the Diaspora has been one of the most uncommon developments in social history and in the present day social process. A people dispersed in all countries of the civilized world has succeeded through twenty-five centuries in preserving to a greater or lesser extent its personal autonomy, adapting it to the most diverse political and social forms of various epochs and countries.

In the ancient Hellenistic cities of Asia Minor and northern Africa the *gerousia* (council of elders) of the Jewish community functioned alongside the Greek city council, the *boule*. The Seleucid and Ptolemaic kings used the self-governing agencies of the Jewish communities for the collection of taxes from the Jewish population. In Alexandria there was even a centralized form of Jewish self-government with ethnarchs, who according to Strabo (first century B.C.) ruled their "own people and secured the enforcement of laws as the ruler of a free *politeia*" (Josephus, *Antiquities*, XIV: vii, 2); a large sized *gerousia*; and a special tax inspector, or *alabarch*. During the early period of Roman rule in western Asia there were frequent conflicts in the cities between Greeks and Jews. The Greek municipalities infringed upon the autonomy of the Jewish communities, which were forced to appeal to Rome for the protection of their rights. Julius Caesar and Augustus took the side of the Jews and ordered their proconsuls to see that the Jews in the cities of Asia Minor and of the Ionian Islands were allowed "to live in accordance with their own laws and the customs of their ancestors," were not conscripted for military service or summoned to court on Saturdays or holidays, that their communal affairs were not interfered with and that they were not prevented from sending contributions for the temple in Jerusalem.

Beginning with the third century of the Christian era the Jewish communities which enjoyed

the broadest autonomy were those in Mesopotamia and the adjoining provinces of the Persian monarchy of the Sassanidae, which later (in the eighth century) became part of the caliphate of Bagdad. Here the self-government was centralized in the hands of two separate powers, the temporal and the spiritual. The exilarch (*resh-galutha*) was the official intermediary in fiscal matters between all Jewish communities and the central government; he appointed judges and administrators in the communities and transmitted their petitions to the supreme government bodies. On the other hand, the learned jurists, heads of the Talmudic academies (*roshe-jeshiboth*) in the Babylonian cities of Nehardea, Sura and Pumbeditha, who received during the Arab rule the title of *geonim*, were officially recognized interpreters of the law and practically the legislators and supreme spiritual leaders of the Jewish people. When a separate Fatimite caliphate had been formed in Arabic Egypt in the tenth century, the Jewish communities there were given their own exilarch with the title of *nagid*; and they had their own *geonim*, who extended their authority to embrace the surviving Jewish communities in Palestine and maintained it there until the conquest of Palestine by the European crusaders.

As the Jewish hegemonic centers were shifted to Europe during the tenth and eleventh centuries the forms of autonomy changed, although its substance remained essentially the same. In Arabic Spain the function of exilarchs was performed by the Jewish ministers at the courts of the caliphs and emirs and in Christian Spain by the Jewish financial or fiscal agents of the kings. Frequently, however, the Spanish kings dealt directly with the Jewish communities (*aljama*). In Aragon and in Castile the rabbis had vast judicial powers. They tried criminal as well as civil suits and could impose sentences of imprisonment, corporal punishment and even death. The constitutions of Jewish self-governing bodies were drafted in conferences of rabbis and lay delegates of the communities, such as that held in 1432 at Valladolid.

Not so broad in scope, although very durable, was the Jewish autonomy in Italy, France and Germany. In the sixteenth century the Jewish communal council (*congrega*) in Rome consisted of sixty members and was headed by three executives (*fattori*) responsible to the papal authority. In France and Germany the system of self-government centered around the rabbis. The German emperors, who regarded the Jews as

Kammerknechte assigned to commercial pursuits with a view to increasing the revenues of the treasury, tried to place at the head of the communities an official who should combine the functions of rabbi and of fiscal agent (*Judenmeister* and *Hochmeister*), but they met with a determined opposition on the part of the autonomous communities. The Jews used to elect from their own midst an intermediary between their communities and the government, known as *shtadlan*, or solicitor; his office was of particular importance at times of persecution on the part of the authorities or of wholesale pogroms. The most prominent *shtadlan* was Josselmann of Rossheim in Alsace in the first half of the sixteenth century, who conducted negotiations on Jewish affairs with Emperor Charles v and with Luther and his associates.

Centralized self-government was carried farthest in the organization of the Jewish communities in Poland in the sixteenth, seventeenth and eighteenth centuries. The unit of self-government here was the *kahal*, or Jewish communal council, which functioned alongside the municipal council of the Christian city. It was an oligarchic institution whose members, elected annually during Passover week, owed their position to either learning or wealth. The *kahal* appointed from its own membership an executive of seven persons (known as *roshim* and *tuvim*, elders and optimates) and several groups of officials: judges (*dayanim*), tax collectors, curators (*gabaim*) of schools, synagogues and charities. In each district (*galil*) *kahals* of the smaller towns were grouped around that of the large city. These district *kahals* were combined in each region or province (*medinah*, *eretz*) into a regional union, which held periodic conferences (*vaad ha-medinah*) for the apportionment of state and communal taxes between the several communities and for action upon other matters of self-government. There were five such provinces in Poland as the country was then constituted: Great Poland, Little Poland, Red Russia and Podolia, Volhynia and Lithuania. These provinces formed in turn a general kahalic union, which met periodically in general congresses (*vaad ha-arotzoth*) attended by rabbinical and secular delegates from the principal Jewish communities all over Poland. The congress acted on constitutional matters, issued regulations (*takanoth*) for communal institutions, passed upon controversies between individual *kahals* and upon grievances of private persons against *kahals* and effected the general apportionment of taxes among the several provinces.

In the seventeenth century Lithuania withdrew from the general kahalic union and formed its own "*vaad* of the principal communities." The two congresses, or *vaads*, functioned as officially recognized Jewish parliaments until they were abolished by the Polish government in 1764 on the eve of the dissolution of Poland as a state.

In the old corporate state the several constituted bodies differed in their attitude toward Jewish autonomy. Whereas the central governments found it advantageous to deal with organized Jewish communities and with their official representatives, who assumed responsibility for the payment of taxes and the enforcement of state laws, the Christian municipal bodies resented this as an infringement of their authority and as a privilege for the benefit of a people which was disliked and which competed with the Christian bourgeoisie in commerce and industry. The kings often had to protect the Jews from hostile action on the part of Christian municipalities, merchant corporations and craft guilds, which endeavored to restrict the most elementary rights of the Jewish population, especially its judicial autonomy. In some instances the kings had to yield to the demand of municipal authorities that the Jews be prohibited from residing in specified places.

The rise of the modern state, based upon the principle of civil equality, and the gradual civil emancipation of the Jews dealt a heavy blow to Jewish autonomy in its old form; that is, to the isolation of the Jewish city (ghetto) from the general municipal administration. The national aspect of autonomy was completely lost sight of; autonomy now had to be confined to religious or synagogal administration. The very act which emancipated the Jews in France in 1791 provides that they shall be granted civil equality on condition that they give up all their former "privileges and special laws"; that is, their former autonomy. Napoleon forced the Sanhedrin of Paris in 1807 to renounce the claims of the Jews to the title of a nation, and he converted the Jewish community through the system of consistories and official rabbinate into a section of the police administration of the city. In Russia and Austrian Poland, where emancipation of the Jews came late, they were in the first half of the nineteenth century deprived of the former kahalic autonomy on the ground that it was an obstacle to their "blending with the indigenous population." On the other hand, the assimilated groups of Jews in western Europe formally renounced national

autonomy; they regarded themselves merely as separate religious groups amidst the dominant nations and were contented with self-government within the limits of "synagogal communities" (*Synagogengemeinden* in Germany; *Kultusgemeinden* in Austria). In America a variety of this type of organization was afforded by the various congregations into which the Jewish population was divided. But the vitality of the idea of Jewish autonomy has been demonstrated by the fact that even those who formally deny it have had in practise to restore some of its institutions. Thus arose such centralized forms of self-government as the communal unions in Germany (*Deutsch-Israelitischer Gemeindebund*; *Preussischer Landesverband Jüdischer Gemeinden*). In fact all those local and central organizations never actually confined themselves merely to functions of church administration but performed many national, political and social functions as well; they founded elementary and higher schools of their own, created institutions of social welfare, reacted to political events and often manifested their solidarity with the Jews of other countries.

With the growth of the Jewish national movement at the end of the nineteenth century the concept of Jewish autonomy received its theoretical elaboration and was advanced definitely as either a complete or a partial solution of the Jewish problem. The doctrine of Jewish autonomism based on the premise that civil emancipation was insufficient to solve the Jewish problem was put forward as a national synthesis supplanting the old thesis of national isolation and its antithesis of assimilation. It appeared first in the countries of eastern Europe where the Jewish masses still employed the Yiddish language and had a network of national schools. Autonomism received a systematic formulation in the writings of Simon Dubnow, who conceived of the Jewish nationality as one bound together by only spiritual and cultural ties and which therefore needed neither a territory nor any other political forms for its national existence. Certain aspects of Jewish autonomism were also developed by Nathan Birnbaum and in socialist circles by Chayim Zhitlowsky, who as leader of the Sejmist party in Russia formulated a program which called for autonomous organization based on a secularized Jewish educational system, the recognition of Yiddish, the spread of agriculture among the Jews and the supervision of such problems as Jewish emigration, hygiene and workers' relief. During the same period the Aus-

trian socialist theorists of national autonomy, such as Renner, Springer and Otto Bauer, established the distinction between the national state with an ethnically homogeneous population and multinational states like Austria-Hungary and Russia as well as the important principle of personal cultural autonomy as distinct from territorial autonomy. This latter principle was especially useful to the Jewish theorists in view of the fact that the Jews represented a nationality that was everywhere in a minority and had no solid settlement within a clearly defined territory. As a result of these developments the alliance of Jewish parties known as the Union for the Attainment of Equal Rights for the Jewish People in Russia demanded during the revolution of 1905 the equality not merely of civil status but also of national rights. Similar demands were made by the national Jewish parties in Austria after the introduction of universal suffrage.

The first attempt to give concrete form to these demands was made in the Ukraine after the revolution of 1917. A Jewish national secretariat and later a Jewish national council were formed and the principle of personal national autonomy was given legal recognition. The civil war, however, put an end to these efforts. As a result of the various treaties after the World War varying degrees of national autonomy were given to the Jewish population in Poland, Lithuania, Latvia, Estonia, Czechoslovakia, Rumania, Greece, Albania and Bulgaria. In Lithuania a Jewish ministry was created in June, 1919, and by the law of March 4, 1920, the Jewish communities received legal sanction to levy taxes and to supervise Jewish educational and cultural activities. As a result of the political changes in 1924 and 1925 most of these institutions were abolished. In general the development of intense nationalism among the ruling nationalities and the force of economic rivalry have tended to reduce most of the provisions for Jewish autonomy in all these countries to a dead letter. Complicating the matter still further is the fact that the Jews themselves are divided on questions of language, religion and on the very problem of Jewish nationality. In Soviet Russia the problem of Jewish autonomy has been dealt with in the same manner as that of other national minorities—on the basis of territorial distribution and language.

JEWISH EMANCIPATION is that development which has been responsible for transforming Jewry from a distinct corporate group, concentrated in urban ghettos and living a social and intellectual life essentially different from that of the surrounding population, into a more or less integral part of the general population among which it resides. In a narrower and more technical sense it is the legal and political development which substituted the principle of equal rights and duties for the previous system of

rights and duties, which were always special in character although they varied from place to place and from period to period. While the term derives analogically from the emancipation of slaves and Catholics (it was apparently first used by Zöpfel in 1831, two years after the British Catholics gained their signal victory), the history of Jewish emancipation is not strictly analogous. This emancipation began to be effective in western Europe and America in the eighteenth, in central Europe in the nineteenth and in eastern Europe (where the great majority of the Jewish people is to be found) in the twentieth century. This drift largely reflected general political and economic developments; the spread of industrial capitalism and democratic institutions was generally accompanied or followed by Jewish emancipation. The slow progress of the emancipatory movement in eastern Europe, however, and its susceptibility to frequent setbacks have been due in part to complex problems arising from the relative density of Jewish population in this region. While emancipation in the wider sense is still incomplete, legal and political emancipation—express or implied constitutional equality of rights—exists for Jews everywhere except in a few backward countries. In such countries as Poland, Rumania and Hungary there is still great disparity between legal theory and practise.

Conscious moves toward equalization of rights began in the eighteenth century, when the development of capitalism made the Jewish merchant and industrial entrepreneur a welcome acquisition to western countries. After the Reformation had established the principle of freedom of conscience and the modern state had begun to transform corporate mediaeval society into a society of more or less equal individual citizens, the legal emancipation of the Jews became inevitable. It was long hindered, however, by the complex structure of the Jewish group, involving peculiar religious, ethnic, social and economic characteristics and especially that purest expression of segregate, corporate life, the extensive system of Jewish autonomy. Non-Jewish opponents of emancipation declared that the existence of the Jewish "state within a state" would always prevent the Jews from identifying themselves with the main body of citizens; some elements of Jewry rejected equality of rights in so far as it endangered their inherited mode of life or their vested interests in the autonomous community. The latter type of opposition was particularly conscious and powerful in Holland

in 1796, in Baden in 1846 and in Galicia from 1848 to 1867; its most representative spokesmen were Rabbis Eger of Posen and Schreiber of Pressburg. Before 1850 frequent consideration was given to a proposal (which was finally abandoned) to distinguish between equality in civil law and that in public law (*privatbürgerliche* and *bürgerliche Gleichberechtigung*) and to remove only the disabilities affecting economic activities while continuing both the political disfranchisement of Jews and their rights of self-government.

Down to the end of the nineteenth century it was generally assumed that there was a necessary connection between emancipation and the assimilation of the Jews to surrounding civilizations. Debate was limited to the question of whether assimilation had to precede emancipation or whether emancipation was to serve as the strongest stimulus to assimilation. As the failure of emancipation to solve the Jewish question immediately bred disillusion and as modern antisemitism and Jewish nationalism arose, the idea of emancipation became divorced from that of assimilation. Equality of rights was now demanded both by Jews and by non-Jews who affirmed that the Jews were an ethnically distinct group. The minority rights guaranteed to the Jewries of several European countries by international treaty and independently adopted by the Soviet Union supplemented in theory the principle of equality. In America and western Europe minority rights in the technical sense were neither imposed by the peace treaties nor are they sought by the Jews themselves. An attempt made at the Council of the League of Nations to extend minority rights to all member countries failed.

The progress of emancipation was frequently stimulated in neighboring countries by states which had already granted equality. Prussia in particular excused several such interferences with the internal affairs of neighboring states by declaring that too many Jews were being attracted to her territories. Humanitarian reasons were frequently voiced, especially in the international gatherings from the congresses of Vienna and Aix-la-Chapelle to the Peace Conference of 1919. The emancipated Jews of the western and later of the central European countries also agitated for the emancipation of co-religionists abroad. After a period of hesitation, during which they had tried to accentuate their new national allegiance by severing ties with Jewries of other countries, came the active inter-

ventions of Sir Moses Montefiore and the Rothschilds for the oriental and east European Jews. In 1860 the Alliance Israélite Universelle was established in Paris to defend the rights of Jews throughout the world. With the same ends in view the British Joint Foreign Committee was organized in 1878, the American Jewish Committee in 1906 and the American Jewish Congress in 1916. At the Versailles Peace Conference in 1919 the Jewish question was raised by the Comité des Délégations Juives, which included representatives from the United States and several central and east European countries and cooperated with delegations of British and French Jews. A Jewish world congress with similar aims has long been debated but never convoked.

Although Holland in 1593 was the first western European country to readmit Jews after the mediaeval expulsions and to grant them extensive rights, it was an Englishman, John Toland, who first advocated full emancipation in his *Reasons for Naturalizing the Jews in Great Britain and Ireland, on the Same Foot with All Other Nations* (London 1714).

Pelham's Jew Bill of 1753, which was to remove the obstacles to the naturalization of Jews in England, provoked such public opposition that it had to be revoked in 1754; and not until 1829 under the impetus of Catholic emancipation was the struggle for Jewish emancipation reopened, with such liberals as Robert Grant, Lord Russell and Macaulay as its chief protagonists. Five emancipation bills adopted by the House of Commons between 1834 and 1857 were rejected by the Lords. In 1858 two House acts enabled Lionel de Rothschild, five times demonstratively elected to Parliament by the City of London, to take his seat. Subsequent amplifications in 1866, 1871 and 1878 opened to Jews the highest government and university offices. In other regions of the British Empire Jews have long enjoyed full equality; in Australia, New Zealand and South Africa, for example, since colonization.

As early as 1740 the Naturalization Act for the British American colonies dispensed with Christian ceremony for "such who profess the Jewish religion." The Virginia Declaration of Rights of 1776, the Constitution of the United States and its First Amendment in 1791 established general equality without specifically mentioning Jews. Remaining minor disabilities were gradually removed by state legislatures, in North Carolina as late as 1868. Most Latin American

republics proclaimed constitutional equality of all citizens in the early years of independence. In the binational parts of Canada there have arisen difficulties concerning the demand for state support of Jewish schools equal to that actually given to the Protestant (English) and Catholic (French) communities.

Of greater significance for the masses of Jews on the European continent was the emancipatory work of the French Revolution. The abolition of the corporal tax by Louis XVI in 1784, the appointment in 1788 of a committee headed by Malesherbes to study the Jewish question, Mirabeau's pamphlet of 1787 on Moses Mendelssohn and Jewish political reform and an essay contest to encourage the discovery of means for making the Jews "happy and useful" held by the Metz Königliche Gesellschaft der Wissenschaften und Künste in 1787 adumbrated forthcoming changes. Discussion of the Jewish question occupied a prominent place within and without the National Assembly from 1789 to 1791. Energetic advocates of emancipation were Abbé Grégoire, Mirabeau, Duport and Robespierre; leading opponents were Abbé Maury, representing conservative and clerical forces, and Reubell, spokesman of the Alsatian third estate, whose *cahiers* had expressed deep grievances against Jewish money lenders. In 1790 Jews of Portuguese and Spanish origin and those of Avignon and in 1791 all other Jews in France were declared full fledged citizens, and the civil equality of individual Jews was maintained even during the revolutionary drive against the various religious creeds.

The impact of these revolutionary measures was soon felt in all territories which came under French domination. The Jews of the Rhineland, Italy and Belgium were automatically enfranchised. Most important in view of its numerical, economic and intellectual importance Dutch Jewry was fully emancipated by the new Batavian Republic in 1796. The slow pace of Jewish assimilation as well as the economic conflict in Alsace led to reaction in France. Aroused by the ethnic tenacity and apparent lack of patriotism of the Jews, Napoleon convoked the assembly of Jewish notables in 1806 and the Great Sanhedrin of Paris in the following year. To twelve questions put by the government the carefully selected Jewish representatives gave answers largely prepared by Napoleon, refusing only to encourage intermarriage as a means of assimilation. In 1808 Napoleon decreed the reorganization of Jewish communal life under rigid govern-

ment control and put the Jews of most French provinces, the Rhineland and Italy under severe disabilities. Modified several times by the emperor, this decree expired in 1818, when even the reactionary government of Louis XVIII did not renew it. After the revolution of 1830 the last vestiges of discrimination were removed by law; beginning in 1831 the national Treasury subsidized the rabbinate, as it did Protestant and Catholic clergy, and in 1846 the Jewish oath (*more judaico*) was abolished. Strangely enough despite the influence of France in stimulating Jewish emancipation in general it is only in the French colonies of Tunis and Morocco (in addition to such backward regions as Abyssinia and Yemen) that the Jews are still legally as well as practically unemancipated. In Holland in 1815 and in Belgium in 1830 emancipation was also supplemented by state subvention to the Jewish cult. In Portugal and Spain, where Jews began to resettle during the nineteenth century, they were not definitely emancipated until the adoption of republican constitutions in 1911 and 1931 respectively. A Spanish decree of 1924 and more emphatically one of 1932 enable descendants of the refugee Spanish Jews of 1492 to naturalize as Spanish citizens regardless of their residence abroad.

In central Europe Jewish equality was demanded by Lessing in his *Nathan der Weise* (1779) and by Christian Dohm in his *Über die bürgerliche Verbesserung der Juden* (2 vols., Berlin 1781-83). Joseph II's Edict of Toleration in 1781 indicated the imperial government's awareness of the necessity of a change in Jewish status. Under the impulse of the French Revolution Westphalia in 1808 and Frankfurt in 1811 granted full equality and several other states granted limited equality. Even counter-revolutionary Prussia removed Jewish disabilities (except exclusion from government office) in 1812.

The period of Restoration, romanticism and the "historical schools" was one of general reaction. Attempts of Austria and Prussia at the Congress of Vienna and the German Diet to establish a uniform liberal policy in the new Germanic Confederation failed; the relevant article 16 of the Acts of Confederation was a compromise, ambiguous at the crucial point. From 1815 to 1824 the struggle between the newly reorganized "free cities" and the Jews assumed international proportions. Although Austria, Prussia, England and Russia, as signatories of the Treaty of Vienna, vigorously and repeatedly protested against anti-Jewish measures, only Frank-

fort was compelled to conclude an agreement with the Jewish community in 1824. Bremen and Lübeck expelled all Jews in 1821, and most other German states failed to grant them a uniform status. Prussia, for instance, retained in the provinces annexed in 1815 twenty different systems which ranged, as did those in the rest of Germany, from full emancipation to full corporate mediaeval segregation. Under the leadership of Gabriel Riesser the struggle entered a new stage with the revolution of 1830. After the extension of Jewish rights by Hesse in 1833, Brunswick in 1834 and Prussia in 1847, the movement was crowned with temporary success through the acts of the Frankfort National Assembly and the Austrian, Hungarian and Prussian diets in 1848-49. Following a few years of reaction, the Austrian and Hungarian constitutions of 1867, a law of the North German Confederation in 1869 and the German imperial constitution of 1871 definitively established equality of rights for all citizens. Since then there have been in Germany and Austria only minor administrative deviations, although the principle itself has been the target of antisemitic attacks from the days of Stöcker and Lüger to those of Hitler. In Hungary, however, where full equality had existed from 1867 until 1919, there have been ever since serious invasions of Jewish rights; and the establishment of minority rights by the Treaty of Trianon in 1920 has provided only a legal solution of the problem. In Czechoslovakia the Jews were granted both equality and minority rights from the outset, but their numerical insignificance in the former Austrian provinces and their conservative mode of life in those previously under Hungarian rule complicate the application of minority rights on the lines adopted for the German and other national minorities.

The restoration of legitimist rulers in Italy in 1815 was accompanied by the restoration of Jewish disabilities. In Rome the ghetto and the Inquisition were reinstated; in Piedmont a law requiring wearing of the badge was almost adopted; Parma alone held to emancipation. The reestablishment here and there of the principle of equality by the revolutionary upheavals of 1830 and 1848 was largely ephemeral; but agitation, initiated particularly by Massimo d'Azeglio, the author of *Della emancipazione civile degli israeliti* (Rome 1847), finally brought about enfranchisement in Sardinia in 1848, in Lombardy in 1859 and in the new kingdom of Italy by its constitution of 1861, which was soon extended

to Venice and Rome. Since then Italian Jewry has enjoyed full equality.

Most Swiss cantons stubbornly resisted even the admission of Jews, until the intervention of foreign powers (the United States in 1857, Holland in 1862 and France especially in 1864) forced the Swiss Confederation to exempt foreign Jews from discriminatory laws. In 1874 the Swiss constitution established full equality of rights. In Denmark the Jews obtained extensive rights in 1814, were admitted to municipal offices in 1837 and achieved full emancipation in 1849. The provinces of Schleswig and Holstein did not enfranchise Jews until 1854 and 1863 respectively. Jews were not allowed to settle in Sweden until 1782, and the attempt of Charles XIV to enlarge their rights failed. They were not permitted to own land before 1860, to vote before 1865 or to hold office before 1870. After the admission of Jews to Norway in 1851 disabilities were gradually removed; from 1891 on Jews were no longer barred from public office.

In the eastern regions of Jewish mass settlement the first signs of forthcoming change were perceptible in Poland during the last years of its independence. In 1882 an anonymous writer influenced by Dohm and Joseph II published in Polish a widely read pamphlet "On the Necessity of Jewish Reforms in the Lands of the Polish Crown." The Quadrennial Diet (1788-91) discussed the question without reaching a definite decision. Even in the short lived duchy of Warsaw, whose constitution of 1807 established the principle of equality in imitation of France, Jewish political rights were abolished after one year. In the part of Poland annexed by Russia agitation for emancipation never went beyond literary controversy, and even after the Jews of Posen and Galicia had been emancipated by Prussia and Austria conditions in Russian Poland remained unchanged except for a minor improvement under Wielopolski in 1862. As a result of the revolution of 1905 and the German occupation of 1915 some disabilities were removed, but full legal emancipation (including the granting of minority rights) awaited the Treaty of Versailles in 1919.

The peculiar structure of Russian society lent to the problem of Jewish emancipation novel and contradictory aspects. At the very beginning of Russian domination Catherine II admitted Jews to participation in municipal government while laying in 1791 the foundation of the future Pale of Settlement. Throughout the following century numerous imperial committees on the Jew-

ish question insisted upon assimilation as a prerequisite of emancipation. There seldom appeared a protagonist of full emancipation among opposition leaders or among the Jews; the Decembrist Muraviev was a rare exception. As industrialization proceeded under Alexander II exceptional laws against the Jews were mitigated, but beginning in 1880 policy was reversed until disabilities reached their height in the May Laws of 1882. Even after the revolution of 1905 Jews although reluctantly granted the franchise continued to suffer from severe discrimination. The revolution of February, 1917, proclaimed the principle of equality, reaffirmed by all the Soviet republics after October. The new independent states of Finland, Estonia, Latvia and Lithuania retained some old Russian laws but were forced to recognize legally the civic and political equality of all inhabitants as a prerequisite of their admission to the League of Nations.

Intolerance brought about international entanglements in Rumania even before that nation obtained full independence. By declaring all but an insignificant minority of Jews to be aliens the Rumanian government evaded the safeguards of general equality imposed by the Congress of Berlin, which had granted the country independence by treaty in 1878. Recurrent interventions of treaty signatories availed little. Only the Treaty of Bucharest in 1918 and more peremptorily those of Saint-Germain and the Trianon in 1919 emancipated the Jews; the last also granted them minority rights.

The other Balkan countries gave Jews full rights after emerging from Turkish domination: Greece as early as 1830, Bulgaria in 1878 and Serbia in 1878 and 1889 (from antecedents reaching back to 1817). Turkey, possessing an altogether different legal system, could proclaim the principle of equality in 1839 and 1856 without thereby altogether abolishing the disabilities of non-Moslems. Emancipation was achieved only by the Young Turk constitution of 1908, which followed western models. In the treaties of 1919-20 also Turkey and the Balkan states assumed international obligations to grant special rights to their minorities. The mandated succession states of Turkey (Palestine, Syria and Iraq) are based upon the principle of equality.

Although equality has been established in all advanced countries and minority rights have been enacted in several, there is often a sharp contrast between theory and practise. In many countries discrimination against Jews exists, especially in regard to public offices and employ-

ment in state monopolies. In many, a legal or administrative *numerus clausus* limits the admission of Jews to universities. A tax burden disproportionate both *per capita* and in relation to economic capacity is frequently carried by Jews. State support for their religious and cultural institutions is frequently negligible. Poland, Rumania and Hungary are the most frequent objects of complaint. In Turkey the government succeeded in persuading representatives of Ottoman Jewry along with those of the other minorities to renounce their minority rights. Although of dubious validity in international public law this renunciation facilitates non-application by the government of the clauses in the peace treaties pertaining to minority rights. It is in the Soviet Union that the principle of combined civic equality and national autonomy has been most completely carried out. While intolerant of the Jewish religion and of Zionism, which along with other religious and political movements it regards as actually or potentially counter-revolutionary, and of the propagation of Hebrew speech, which it regards as an accessory of political Zionism and an expression of bourgeois culture, the Soviet government encourages Jewish national and *yiddishist* cultural developments. Whole administrative districts are now Jewish in a national sense and projects for a Jewish republic, to enjoy equal status with other federated socialist Soviet republics, have been developed.

The effects of emancipation upon Jewish life have been marked throughout the world. The removal of disabilities has brought about a great economic restratification. While Jews were previously almost totally excluded from agriculture, the proportion of farmers among them rose to about 2 percent in 1900 and is almost 5 percent today. General admission to the medical, legal and teaching professions and to public offices as well as their induction into the cultural life of the surrounding nations has opened a vast range of opportunities to Jewish intellectuals. Nevertheless, the proportion of Jews in commercial occupations everywhere remains larger than their proportion in the population. The transition from craft to heavy industry has also been very slow among Jews except in the Soviet Union. As a whole, however, the preemancipation economic contrast between Jews and Gentiles is steadily disappearing.

In some countries rapprochement between Jew and Gentile resulted in a tremendous increase of intermarriage. At its highest, in Trieste in 1927 every other Jew or Jewess married a

Gentile. In Copenhagen and Hamburg the proportion is one third, in Germany as a whole one fifth, in the interior of Russia one sixth. In America, where it reached one sixth before 1880, it dropped suddenly during the "Russian immigration" of the 1880's but is again increasing. In the east European mass settlement, including White Russia and the Ukraine, however, it ranges between 1 and 5 percent. Perhaps in part because of an apparent low fecundity of such marriages, the change in the racial composition of the Jews is still comparatively small.

In the communal life of Jewry emancipation meant the abolition of the traditional form of self-government. In countries such as the United States and France the separation of state and church resulted in the substitution of freely organized congregations for the official communities in which membership was compulsory. In most European countries the community was retained, but its range of activities was limited to the religious field, a term under which was included a variety of competences. For instance, in eastern Europe and Palestine the community continues to exercise considerable control over marriages and divorces, birth registration and social work. In cultural life the transformation was the more obvious the more readily the Jews adopted the language of the surrounding population and partook of its cultural life. Even in "purely" Jewish expressions, such as Hebrew and Yiddish letters, the influx of foreign ideas and the adaptation of foreign patterns is fully evident. The early reform movement in Germany and the United States was an extreme application of emancipation to religious life, and the emancipation influenced even conservative and orthodox Jewry. The present religious crisis in Judaism is due not only to antireligious tendencies of the age but also to the impact of emancipation.

Jews are almost unanimously in favor of legal emancipation. Even Zionists, who formerly despaired of Diaspora life and demanded "self-emancipation" instead of emancipation from outside, today insist upon equality of rights in the Diaspora. As to emancipation in a wider sense opinions differ. While assimilationists of all shades favor it, both Zionists and Diaspora nationalists reject it, in so far as it implies loss of Jewish national identity. For them only the combination of equality and national minority rights presents a more or less satisfactory solution. But while Diaspora nationalists regard such a development as a definite and desirable solution of

the Jewish problem, Zionists postulate a Jewish homeland to supplement it.

JEX-BLAKE, SOPHIA (1840-1912), British feminist and physician. After struggling to obtain an education Sophia Jex-Blake determined to found a college for women and for this purpose traveled in Germany and America. From

Dr. L. Sewall of Boston she received her first insight into the pressing need for women doctors, and although she had earlier rejected the suggestion of a medical career she made an unsuccessful attempt to enter Harvard Medical School. She next sought entrance to the University of Edinburgh and with ready speech and a biting pen surmounted the difficulties of examining boards and hospital committees and won a legal decision against the university in 1869 permitting her to study medicine there—only to be repulsed when the university obtained on appeal a judgment pronouncing the concession illegal. Ignoring the advice of those who urged that the time was not opportune in Britain she engaged in spectacular agitation to gain the right for women to study medicine. In 1874 she founded the London School of Medicine for Women, in 1876 succeeded in getting an act passed enabling universities to admit women medical students and in 1877 took her own degree at Berne. Her fighting qualities and singleness of purpose won popularity for the woman's education movement, but her uncompromising spirit alienated many from her and prevented her from winning fame as a doctor. Through her efforts the School of Medicine for Women and the Dispensary for Women and Children were established in Edinburgh.

JHERING, RUDOLF VON (1818-92), German jurist. Jhering was successively professor at the universities of Basel, Rostock, Kiel, Giessen, Vienna and Göttingen. He began his career as a Romanist but developed into the most encyclopaedic mind in German law in the nineteenth century. His self-willed character and volatile temperament prevented his founding a dogmatic school, but possibly for that very reason he exercised a continuous influence upon the generation which followed him.

Jhering is of importance not only to jurisprudence but to sociology. While during his lifetime almost all other jurists remained within the narrow, formal bounds of their science, he was animated by the problem of the meaning of law for life. He did not, to be sure, begin in this way: in the first half of his career he too believed that the law was a self-contained system; it was only

necessary to know the logically constructed legal concepts to be able to solve any new problem of law by a process of dialectic. About the age of forty, however, he began to destroy that which he had hitherto regarded as sacred and sought to remove law from its position of isolation and to place it in the midst of the current of life.

The individual is the starting point of Jhering's philosophy. In his most celebrated work, *Der Kampf ums Recht* (Regensburg 1872, 19th ed. Vienna 1923; tr. by J. J. Lalor, 5th ed. Chicago 1915), which has been translated into twenty languages, he taught that an attack upon an individual's legal rights was at the same time an insult to his personality and that he was consequently under a moral duty to repel the attack. But even here the striving for the idea of community is already apparent: the assertion of the law is a duty that the individual owes to society. Jhering proceeded in the same manner in his most important work, *Der Zweck im Recht* (2 vols., Leipsic 1877-83; 4th ed. 1905; vol. i tr. by I. Husik, Boston 1913). Egoism is the unavoidable point of departure for all law, but it is not unreconcilable with the needs of the world, which enlists the individual in its service by giving him the reward that he desires. As long as the world attracts him to its purposes it can be sure of his cooperation. This enlistment of the service of the individual was the very basis of culture. At another time Jhering expressed the same ideas in his declaration that the three pillars of the law were the propositions "I exist for myself," "The world exists for me" and "I exist for the world." From the first he derived the whole law of persons; from the second the law of property, family law and the law of obligations; and from the third the concept of duty. He even projected the ideas, although only incidentally, into international law upon the analogy that the individual nations existed for the purposes of the world. To Jhering the state stood, so to speak, in a subordinate position; it was society that was the supreme concept. The state interfered by means of law only to protect the order which was determined by the purposes of society. Purpose was the creator of law. Moreover the law was not the only determining force: Jhering was interested particularly in such ethical factors of social intercourse as decorum and politeness. It is thus seen how strong was the sociological trend in his thinking.

Entirely new, considering the position of the jurists of his time, was Jhering's treatment of property. He does not deny—indeed he defends

—the right of private property. But unlike most of the contemporary jurists, who steeped in the Roman law attributed absolute powers of disposal to the owner, he insisted that it must be subordinated to social needs. Attacking the problem of possession in his *Beiträge zur Lehre vom Besitz* (Jena 1868; 2nd ed. 1869, with title *Über den Grund des Besitzesschutzes*) and over twenty years later in his *Der Besitzwille, zugleich eine Kritik der herrschenden juristischen Methode* (Jena 1889) he reacted against the conceptualism of the prevailing "will theory" and pointed to the social factors which had historically determined the protection of possession.

In addition to these works must be mentioned Jhering's celebrated *Der Geist des römischen Rechts auf den verschiedenen Stufen seiner Entwicklung* (3 vols., Leipsic 1852-65; 5th-6th eds. 1906-07), the significance of which he himself expressed in the motto, "Through the Roman law but beyond it." Jhering's strong sense of humor, which achieved satiric heights, is reflected best in his spirited *Scherz und Ernst in der Jurisprudenz* (Leipsic 1885, 10th ed. 1909). In 1857 he founded with Gerber the *Jahrbücher für die Dogmatik des bürgerlichen Rechts*, which is still held in high regard. Almost all of Jhering's works have had influence beyond Germany, and the contemporary world may still find in him a source of inspiration.

JIHAD, the battle on the path of Allah, approximates the western concept of holy war. Its history goes back to the early days of Islam when the religious obligation to disseminate the faith—either by persuasion or, failing that, by the

sword—explains in large part the tremendous momentum of early Islam and the unprecedented, triumphant growth of Mohammed's religion only a few decades after its founder's death.

Mohammed himself did not propound the obligation on such a scale. There is no mention of the jihad in the oldest portions of the Koran: the suras of the Meccan period preached patience in the face of attack because at that time no other attitude was possible. It was only in Medina, after Mohammed had become the leader of an entire community, that he commanded his adherents to return blow for blow and even to begin war independently. The Koran in speaking of the jihad against unbelievers often calls the latter unfaithful and dangerous, and Mohammed appears to have been less interested in their conversion than in their subjugation. They were to be fought not so much because of their unbelief as on the ground that they were hostile to his adherents. Thus the Koran (II: 186) states: "And fight for the cause of God against those who fight against you; but commit not the injustice of attacking them first: verily God loveth not the unjust."

Shortly after the death of the prophet, however, the war against unbelievers as such developed into a religious duty; numerous passages in the Koran were cited in which Allah using Mohammed as a mouthpiece commanded a struggle against the unbelieving Arabs. The jihad became accordingly almost a sixth "commandment" (*ruk'n*) and was in fact subsequently accepted as such by the descendants of the so-called Kharijites. Such a development was to be expected in a militant religion which arose among a warlike nomad people. It also became a political necessity, for after Mohammed's death a number of tribes weakened in their allegiance to the theocracy and external expansion seemed the best way of remedying the situation. The holy war with its promise of spoil made Islam understandable to the Bedouins and won back their loyalty and support, and the religious impetus in turn gave strength to the wars of conquest.

The jihad was to be supervised or led by a Moslem sovereign, or imam, and the entire world considered to be divided into the *dār al-ḥarb*, the war area where Moslems were not in control, and the *dār al-islām*, or the regions already under Islamic rule. Theoretically the Moslem state was at permanent war with the non-Moslem world. Hence it was the purpose of

the jihad to transform the *dār al-ḥarb* into the *dār al-islām*. The implications of this concept were of course never completely realized and Moslem theologians were compelled very early to adapt the doctrine to changing needs. A people against whom a holy war was to be waged were first summoned to embrace Islam. In case of refusal they had the choice of submitting or fighting. In the first case they were granted mercy with certain limitations, whereas in the second they might expect the loss of their freedom as well as of their property. From the very beginnings of Islam large numbers of people of other faiths inhabited the Islamite areas and special provision was made for believers in religions based upon revealed scriptures, especially Jews and Christians, to allow them to enter into a protected relationship with the Islamic empire. Upon the payment of certain taxes they were guaranteed the free exercise of their religion as well as the safety of their lives and property. In fact their lives and property had to be defended to the end against enemies.

Gradually the whole doctrine of the jihad was modified, and at present it is interpreted as a joint and not an individual duty of all free, male, adult Moslems sound in mind and body who have the means to reach a Moslem army; this duty will continue to exist until the entire world has been subjected to Islam. It is held, however, that the obligation is fulfilled when a certain number of the faithful comply with it, and that the religious law is satisfied if a Moslem sovereign undertakes one campaign annually or even if he makes preparations for war and sees to the preparedness of the army. The imam alone is empowered to direct the jihad; and in cases such as that of the Shiites, whose imam is at present considered invisible, there can be no jihad until the imam reappears. If a Moslem country is invaded by unbelievers, the imam may issue a general call to arms to all the Moslems in the country and in case of need this summons may be extended to embrace the entire Moslem world. As territories once Moslem have come under the control of non-Moslems, however, the position has been taken that they do not become *dār al-ḥarb* except under certain conditions, the most important of which is the non-observance of legal decisions of Islam. When these conditions are violated the country must be won back or Moslems must emigrate from it.

These doctrines reflect those changes in the political and economic background of Islam which have not only influenced theory but have

also profoundly affected the jihad as a realistic force. While the duty of war conformed to tribal custom, the jihad remained a source of strength to Islam. The promises of rich rewards for those who die battling for the faith, depicted in the Koran and more vividly in the traditions (Hadith), naturally increased tremendously the courage and the contempt of death on the part of Moslem warriors. The belief in the martyrs' bliss has raised the courage of Moslem soldiers to an often unbelievable degree even down to recent times. Nevertheless, the significance of the jihad diminished consistently as Islam was accepted by large settled populations and as the Arabs themselves ceased to be a segregated military group. The doctrine of the holy war was based moreover upon the assumption of a unified Moslem religious-political state, an assumption which soon proved false. Various religious groups arose under rival imams, and even at the time of the Abbassides the empire was a very shaky structure which rapidly dissolved into a large number of rather independent governorships and sultanates. The Ottoman Empire, which united under its scepter most of the former Abbasside provinces as well as large new areas reaching as far as the gates of Vienna, was difficult to control and disintegrated rapidly during the nineteenth and the early twentieth century. The sense of unity, very strong in the past, was never able to take the place of an organized ecclesiastical union, which was thwarted by political circumstances as well as by the cultural level of the Moslem peoples.

The collapse of the jihad as a significant force was made clear in 1914 when the Ottoman sultan in his capacity of caliph summoned the whole Moslem world to a holy war against the Entente powers. The fact that Turkey was acting in alliance with infidel countries gave the command an unorthodox flavor and the only Moslem rulers to respond were the great Sanūsi and the imam of Şan'a. The enemy side endeavored scientifically to disprove the dubious claims of the caliphate; in fact the Moslems in countries controlled by the Entente could not have joined the Ottoman armies if they had wanted to. The pan-Islamic propaganda of the pre-war years bore little fruit, and it was probably the growing strength of nationalism among Moslem peoples which as much as any other factor played havoc with the Turks' appeal for Islamic unity and made possible the anomaly of Indians and Arabs fighting with Christian powers against their Turkish brethren in the hope of furthering their

own national interests. The summons to a jihad remained confined to Turkey; elsewhere there were only a few resolute and devout Moslems who were not deterred from rushing to arms.

Since the World War the jihad has had even less practical importance, especially since the abolition of the caliphate and the disintegration of the Ottoman Empire. Certain movements within Islam, such as Wahhabism in southern Arabia, still retain the jihad in their program, but modern theologians tend in general to diminish or discredit it. As a practical matter under present political conditions in the Orient a holy war for the further spread of Islam is entirely out of the question. Just as attacks were repeatedly made upon Turkey during previous centuries without being immediately denounced as attacks upon the caliphate and without all the Moslems being summoned to the defense, an aggression against a Moslem country in the near future will scarcely cause the unified Moslem community to rise against the invader.

JĪMŪTAVĀHANA, Hindu jurist. He was the founder of the Bengal, or Gauriya, school of law, which flourished probably from about 1090 to 1130. The acceptance of these dates, which are based on astrological minutiae in his works and on traditions of his descent and of his position

as chief justice and minister of one of the Sena kings of Bengal, leads to the assumption that Jimūtavāhana's legal eminence was only tardily recognized. Although he quotes no writer later than the twelfth century, he himself is not quoted until the fifteenth century; the earliest of his known manuscripts dates from the close of this century, and in fact Jolly and others assign him to this later period.

Three works of Jimūtavāhana are extant: the *Kāla-vivēka* (ed. by P. Tarkabhūṣana, Bibliotheca Indica, n.s., vol. lxix, Calcutta 1905), on the determination of the calendar and auspicious times and seasons; the *Vyavahāra Mātrikā* (ed. by A. Mookerjee in Asiatic Society of Bengal, *Memoirs*, vol. iii, 1912, p. 277-353), on judicial procedure; and the *Dāya-Bhāga* (tr. by H. T. Colebrooke in *Two Treatises on the Hindu Law of Inheritance*, Calcutta 1810, p. 1-240), literally "division of inheritance." Although Jimūtavāhana nowhere expressly names the *Mitākshara* of Vijnāneśvara (tr. in Colebrooke's *Two Treatises . . .*), an omission comprehensible in a contemporary but inexplicable in a fifteenth century writer, he unquestionably wrote the *Dāya-Bhāga* to combat certain doctrines of which that jurist was the protagonist. He negates the distinction between ancestral and self-acquired property; between unobstructed inheritance, the right to which accrues at birth, and obstructed inheritance, the right to which accrues only after the death of the property holder. He denies the doctrine of birth rights and replaces the Hindu paterfamilias on the pedestal which he occupied earlier in the *Manusmṛti* as the unrestricted lord of the family property. The sons cannot demand a partition against his wishes; he may sell them into slavery and has rights over their personal earnings; he may spend or divide the property in his lifetime, even *mortis causa*, although not, strictly speaking, by will. It follows that father and sons do not in law constitute a joint family. In the same uncompromising individualism the members of the joint family are regarded not as joint tenants but as tenants in common. Their shares are freely assignable, and a childless widow succeeds to a share as the heir of her husband. On the other hand, if her husband dies before acquiring his right, she is not legally entitled even to maintenance. Jimūtavāhana's touchstone for the right to inherit is the duty to offer oblations to departed ancestors. In outline his scheme differs little from that of the *Mitākshara* for obstructed inheritance; but his theory

enables him to prefer the father to the mother and the daughter who has or is still capable of male offspring to one who is not. The duty of oblations to maternal ancestors serves as a peg to introduce a select list of cognates for a higher place in the scheme of inheritance than *Vijnāṇeśvara* allows. Finally, *Jīmūtavāhana* says "An accomplished fact outweighs a hundred texts," which, however, means no more than *factum valet quod fieri non debuit*: the exercise of a legal right is not barred because in a particular case it happens to be the breach of a moral duty. Some Bengali scholars have argued against the prevailing acceptance of this text and have endeavored to show that the *Dāya-Bhāga* differs less from the *Mitākshara* than is commonly supposed. These views, however, have not carried general conviction even in Bengal, although it is unquestionable that the sentiment of the *Dāya-Bhāga* joint family is nearer to the *Mitākshara* than the bare letter of the law. The system of law which *Jīmūtavāhana* propounded is still followed by Bengalis and is administered for them by the British courts.

JINGOISM. *See* CHAUVINISM.

JIREČEK, JOSEF KONSTANTIN (1854–1918), Austro-Czech historian. Jireček was born in Vienna of a family of celebrated Czechish scholars. He studied at the University of Prague and lectured there as *Privatdozent* from 1877 to 1879. His historical interests centered almost exclusively about the Balkan peoples in the Middle Ages; at first he devoted his attention to the Bulgars and Serbs, then for a time only to the Bulgars and later in an increasing degree to the southwestern part of the Balkan Peninsula—the Serbs, Balkan Romans and Albanians—and Byzantium. Political, social, economic and cultural history as well as historical geography and ethnography were included in the scope of his researches. His first major work, *Die Geschichte der Bulgaren* (Prague 1876), written at the age of twenty-one and at a time when the Bulgarian question was to the fore, secured him a world

wide reputation and special recognition in Bulgaria. In 1879 the Bulgarian government invited him to Sofia. In the course of his five years' activity as secretary general of the Ministry of Education, as minister of education and as director of the National Library he won lasting renown in the organization and extension of the entire Bulgarian educational system. His work was especially significant in regard to the primary and intermediate schools and cultural institutions (the university, the National Library, the National Museum and the Bureau of Statistics). His fame rested also upon his valuable advice in the formation of the modern machinery of governmental administration. The profound first hand knowledge of the Balkan Peninsula which he acquired through his influential position and extensive travels led him to write *Das Fürstenthum Bulgarien* (Prague 1891), which is still essential for a study of Bulgaria. In the succeeding decades he was active in Prague and Vienna, became increasingly interested in Ragsan, Serbian and Byzantine history and after exhaustive research in the rich Dalmatian archives treated the most complicated problems of Balkan, Roman and Albanian history. He not only collected an enormous mass of entirely new historical facts but also laid the foundations of present day knowledge of the ancient history of the Balkan Peninsula. After his great work on the Romans in the cities of Dalmatia, which is of basic importance for late Roman, Byzantine and mediaeval western history, ethnography, topography and linguistics, he composed his masterpiece, the *Geschichte der Serben* (*Allgemeine Staatengeschichte*, pt. i, no. 38, 2 vols., Gotha 1911–18), which carries the narrative to 1537 and is still the best work on the subject; it complements his "Staat und Gesellschaft im mittelalterlichen Serbien" (*Kaiserliche Akademie der Wissenschaften, Vienna, Philosophisch-historische Klasse, Denkschriften*, vol. lvi, 1912, nos. 2–3, vol. lviii, 1914, pt. ii, and vol. lxiv, 1919, pt. ii), which extends to 1459 and is equally fundamental for the older cultural history of the Balkans and southern Slavs, especially of the southwest.

Jireček was the most important representative among the Slavs of the German critical method in historical science and is recognized as the leading authority on the past of the Balkan Peninsula, its historical geography and ethnography. The originality and importance of his contribution to Balkan historiography proceed from his critical examination of sources, espe-

cially archives; his break with the constructions and hypotheses based on the former combination of history and philology; and the extended scope of his researches and observations whereby he secured a mass of separate pieces of information and was able to correct former concepts concerning the most difficult problems; but especially from the fact that he supported political data by legal, socio-economic and historico-ethnographic data and that in his works on cultural history he emphasized as fundamental socio-economic and legal relations. He thus succeeded in demonstrating to what extent western influences prevailed along with the Byzantine in the governmental as well as the social and economic structure of the Balkans.

JOSEF MATL

Consult: Murko, M., in *Neue österreichische Biographie*, vol. i (1918-19) 537-97; Zlatarski, V. N., in *Bulgarska Akademiya na Naukite, Lietopis*, vol. iv (1919) 85-110; Radojčić, N., in *Narodna starina*, vol. vi (1923) 193-216.

JITTA, DANIEL JOSEPHUS (1854-1925), Dutch jurist. Jitta was educated in Holland and Belgium; after a period of law practise he became professor of commercial and private international law at the University of Amsterdam. Subsequently he served as a councilor of state at The Hague.

His writings, which are characterized by a cosmopolitan, somewhat idealistic spirit and by a philosophy of tolerance and reconciliation, are significant contributions to the theory of private international law. The most important are: *The Method of Private International Law* (The Hague 1890); *The Substance of Obligations in Private International Law* (2 vols., The Hague 1906-07); *The Renovation of International Law, on the Basis of a Juridical Community of Mankind* (The Hague 1919). Jitta regarded mankind not only as a *de facto* community but also as a *de jure* community which should be governed by principles based upon the requirements of the universal social group. These principles are the fundamentals of international law and aim at establishing a universal reign of law. They must be respected by the states, which derive their sovereignty from mankind itself and are obligated to insure order not only for their own national local groups but also for all society. Private international law should not be called the "conflict of laws" but rather "private law considered from the point of view of what the juridical community of mankind demands,"

since the solution of conflicts is not its aim but only an expedient. In the sphere of private law he distinguishes between the relations which are relatively international and those which are absolutely international. The first are relations of foreign origin, existing between foreigners, in which the foreign law applies; except where it conflicts with the public policy, order and morals of the state in which the case is being adjudicated. The absolutely international relations are those which do not belong preponderantly to the juridical life of any single state but which affect more than one. Here the rules of the common international law are applicable. Frequently they can be formulated by resolving the conflict of laws and adopting the law of one of the competing states. Sometimes, however, this method is not satisfactory and then a fully independent, newly formulated rule should be adopted. In settling questions of private international law the rule suitable to the universal society of mankind applies by virtue of reason, except when the positive law of the state in which it is adjudicated is opposed to it; for the judge is bound by the positive law of his own state.

JOACHIM OF FLORA (c. 1131-c. 1202), Calabrian mystic and prophet. Legends have sprung up luxuriantly about the name of Joachim of Flora, but nothing is certain concerning his life except that he was born at Celico of humble parentage, that while still very young he entered the Cistercian order shortly after the reconciliation of Roger II of Sicily and St. Bernard and that he later abandoned it to found a monastic congregation more faithful to the rigorous Benedictine rule. Although a renegade from the Cistercians Joachim represented and expressed better than any other figure the democratic and cooperative ideas of organization which the Cistercian movement was propagating throughout Europe in opposition to feudalism. In Joachim's interpretation of the Bible may be found a repercussion of these ideas. Joachim divides revelation into three stages, each corresponding to a historical epoch: the Age of the Father, or of the Old Testament; the Age of the Son, or of the New Testament; and the Age of the Holy Ghost, or of the future. The first was

the time of spouses—that is, patriarchs and kings—and of slaves; the second of freemen and priests; the third and final era would be that of friends and mystics, living without class or social distinctions. The visible church of Rome, to which Joachim ascribed a merely symbolical and provisional function, would according to his reckoning have fulfilled its function in 1260. In that year it would collapse, making way for the new epoch of equality and peace, which would be ushered in by a purified monachism. Thus at a time when the revival of trade was everywhere sharpening the acquisitive sense Joachim resurrected the message of primitive Christianity. In 1254, following the attempt of a fervent disciple to give the Joachite faith a canonical form with the fatidical title of *Evangelium aeternum*, Rome condemned Joachism. But the faith, which had reverberated throughout Italy and southern France, survived the condemnation. The Spirituals of the Franciscan order were led by the striking similarity between the Franciscan religion and the Joachite Age of the Holy Ghost to proclaim Francis as the inaugurator of the third era. Joachism became the creed of the Spirituals and of the Fraticelli; and it was a logical consequence of their Joachite faith that these groups became fervent advocates of poverty and communism. Through them it continued to be a vital element in the spiritual atmosphere of Italy and southern France until, after experiencing an illusory realization under the brief pontificate of Celestine V (1294), Joachism and with it mediaeval ecclesiastical communism were finally overwhelmed by the persecutions under Boniface VIII (1294–1303) and John XXII (1316–34).

JOHANN MORITZ, FÜRST VON NASSAU-SIEGEN (1604–79), German colonial administrator. Johann Moritz was born in Dillenburg and after an excellent Calvinistic education in Germany and Switzerland achieved distinction in the Dutch army. In 1636 he was made governor of "New Holland," the Dutch West India Company's foothold in northern Brazil. The company, organized primarily as a military weapon to weaken Spain by threatening and appropriating its bullion supply, had chosen the more vulnerable Portuguese part of the Spanish empire in America as the main object of its attack. It had acquired New Holland after a hard struggle, but the colony was grossly neglected until the failure of the company's freebooting enterprise to cover expenses led the directors to seek an added source of revenue in sugar production. For the task of transforming New Holland into a colony with a developed social and economic life Johann Moritz was eminently qualified by his statesmanlike vision and his military talents. He pushed back the Portuguese and greatly increased the area of the colony. He placed all responsible posts in reliable hands, furthered Protestant missions, organized the care of the poor, built schools and brought scholars and artists to the capital, Mauritsstad. The Portuguese planters who had fled were guaranteed free exercise of their religion and assured of the return of their property. For a time, however, many were afraid to return; the government sold the unclaimed sugar mills and plantations at auction on long term credits and by conquests in Africa provided an adequate supply of slave labor on similar terms. On the governor's advice the company's all inclusive trade monopoly granted in 1621 was restricted in 1638 to the importation of slaves and ammunition and the export of brazilwood. All these favorable conditions brought many settlers, among whom Portuguese Jews predominated. The governor attempted to maintain friendly relations among the Dutch, Portuguese and natives; but the unwise agitation of Calvinist zealots, the encroachments of soldiers and the company's officials on the population and above all the growing indebtedness of the planters gave rise to increasing dissatisfaction. The danger of the situation was aggravated when the directors, burdened with a badly paying colony, ordered a diminution of the defense forces and an increase of the sugar export. Finally they suspected Johann Moritz of seeking to create a principality for himself, and he resigned in 1644. When Portu-

guese revolts culminated in the loss of Brazil in 1654, the miserable planning and support of the company's Brazilian enterprise were fully revealed.

JOHN DUNS SCOTUS. *See* DUNS SCOTUS, JOHN.

JOHN QUIDORT OF PARIS (d. 1306), mediaeval theologian and political theorist. John was a Dominican in St. Jacob in Paris and late in life he became a licentiate at the University of Paris. He is the author of a commentary on the *Sentences* of Peter Lombard and of other theological works which mark him as a penetrating and independent thinker. His chief political work is his *Tractatus de potestate regia et papali* written in 1302 or 1303 during the controversy between Pope Boniface VIII and Philip the Fair of France. John, although not extreme in his claims, took the side of the king and particularly attacked the views of such defenders of the pope as Aegidius Romanus, James of Viterbo and Henry of Cremona. Seeking a middle position between the extreme adherents of the doctrines of temporal and spiritual supremacy, he held that church and state are each independent within their respective spheres although there is a reciprocal influence between them. While allowing for the material basis of the church John maintained that its authority should be limited to spiritual matters. A sharp analysis of the essence of spiritual power, he declared, reveals that it does not involve the use of secular authority or of force but is confined solely to the exercise of moral influence. The church, it is true, may possess temporal sovereignty and jurisdiction but only when so endowed by the state. It can punish offenses against the church only indirectly by persuading the temporal power to take action against the offenders. John recognized the divine basis of the papal authority but asserted that the spiritual powers of the bishops and priests are likewise derived directly from God. The pope is not the absolute ruler, but only the responsible

leader of the universal church which is made up of a series of communities and churches. Possession of church property is always vested in these communities and churches and not in the hands of an individual, even though he be pope. John favored a representative and constitutional organization of the church with the college of cardinals, the emperor and the general council possessing the power to limit the rule of the pope and if necessary to depose him. The general council, not the pope, is the supreme authority in matters of faith. Germs of the conciliar theory are undoubtedly present in John's theories; Gerson and others were influenced by him and Bellarmine cites him as the representative of the most moderate theory concerning church and state relations.

In his political philosophy John is a follower of Aristotle and Thomas Aquinas but he emphasizes the social contract and restricts the ethical ends of the state to the moral and not the theological spheres. The ideal form of political organization is the national state with a representative form of government. He attacked the idea of a universal empire and declared the Roman Empire to be extinct.

JOHN OF SALISBURY (c. 1120-80), English churchman and scholar. John, author of the first treatise of strongly sacerdotal tendency written in England, was, in Stubb's words, "the most learned man of his day." Trained at Paris, where he attended the lectures of Abélard, and at Chartres, John divided his official career during the period from 1148 to 1159 between the papal court and the service of Archbishop Theobald of Canterbury. In 1159 he remarked that he had crossed the Alps ten times since he first left England. That year he fell under the displeasure of Henry II and was deprived of some of his official duties, an event which gave him time to complete his two main works, the *Policraticus* and

the *Metalogicus*. The latter describes his student years and early philosophical pursuits; the former, headed also *De nugis curialium, et vestigiis philosophorum*, enunciates two political doctrines—the distinction of the legitimate prince from the tyrant and the subordination of the imperial to the priestly authority. The prince is not absolved from obedience to law; his position is that of “a minister of the public welfare and a servant of equity,” since the state exists to promote equity. From the church the prince receives the whole authority he wields. The fifth and sixth books are based upon a work called by John *Institutio Traiani*, from which he draws a lengthy comparison of the state with the human body: the head is the prince, the soul the priesthood. But if John was a sacerdotalist he was also a genuine Englishman, as can be judged by the remark that we must normally tolerate the weaknesses of our rulers and by his invectives against clerical rapacity.

Soon after the Council of Clarendon in 1164 John found it expedient to leave England. In this year he began to revise his remarkable *Historia pontificalis*, which carried on from the year 1148 the Gembloux continuation of Sigebert's chronicle. For the next six years he lived with his friend Peter de la Celle at Reims. From abroad he did his best to reconcile Becket with the king; and when peace appeared to be in sight he returned in November, 1170, and was with the archbishop at Canterbury when the murderers entered the cathedral. In 1176 he became bishop of Chartres and in 1179 attended the Third Lateran Council.

JOHNSON, GEORGE (1837–1911), Canadian statistician. Johnson entered upon a journalistic career in Halifax, became editor of the *Halifax Reporter* and then Ottawa correspondent of the *Toronto Mail*. An early advocate of the confederation of the Canadian provinces, he took a prominent part in the troubled politics of the Maritime Provinces in the confederation era; subsequently he strongly espoused the adoption of protection as a Canadian national policy and the building of the Canadian Pacific Railway. His first official position was that of chief census commissioner for Nova Scotia in 1881. From 1887 to 1906 he was chief government statistician and directed the taking of the third census of the dominion in 1891. In 1886 he was instrumental in founding the official *Statistical Year Book of Canada*, and he edited the issues for the years 1892 to 1904 inclusive. The *Statistical Year Book* was a noteworthy compilation for its day; Johnson realizing that the state is not a series of heterogeneous activities was among the first to grasp the importance of a general purview in statistical organization. His memoranda to this end, and in particular one which was officially printed in 1890, were of pronounced effect.

Johnson also edited *The All Red Line: the Annals and Aims of the Pacific Cable Project* (Ottawa 1903).

JOHNSON, JOSEPH FRENCH (1853–1925), American pioneer in commercial education. Johnson's most significant work lay in organizing the teaching and the training of teachers of business subjects. Under his guidance the School of Commerce, Accounts and Finance of New York University, of which he was dean from its early formative years until his death, expanded steadily. The success of the Alexander Hamilton Institute, which he founded in 1909 to bring his

teaching material and methods by means of home study to people actively engaged in business, indicates how effectively he met the need for executive training. As a teacher Johnson made the principles of economics understandable to the business man through vivid concrete illustrations of business problems. Here his early experience as a journalist stood him in good stead. He felt, however, that economics for the business man should include not only a presentation of the general principles but an inductive and descriptive study of specific fields of economic activity. To this end he organized at the School of Commerce groups of courses in such subjects as accounting, banking, investments and corporation finance, a grouping which is now found in all collegiate schools of business. For the same purpose he edited for the Alexander Hamilton Institute a popular series of texts on *Modern Business*. Throughout his work as teacher and organizer Johnson insisted on economic theory as a basis for the more specialized fields of study. He believed, however, that those engaged in business were especially interested in and in many respects best qualified to study the science of business. In his own work as a member of the National Monetary Commission, in his writings on questions of money and banking and in his studies of governmental control of business activity Johnson stressed the importance of economics in the practical affairs of business and statecraft.

A. WELLINGTON TAYLOR

JOHNSON, SAMUEL (1709-84), English journalist, lexicographer, critic. Johnson has been called the first "man of letters" in the sense that he made all of literature his field and pursued it as a profession, disdaining the support of patronage. The famous letter to Lord Chesterfield in fact has been held to symbolize the end of literary patronage as a means of subsistence for the writer. For the latter half of his life Johnson was the dominating force in English letters, ruling taste, fixing a prose style and enforcing his personality to an extent that well merited his nickname of the "Great Cham." His *Dictionary of the English Language* (2 vols., London 1755; new ed. by P. A. Nuttall, London 1855), published after eight years of prepara-

tion, was the first English dictionary to be compiled with a scholarly and profound talent for definition despite the current ignorance of etymology. It was an important influence in molding English usage, and even today, although the works of specialists have surpassed it in many ways, it remains a masterpiece in clarity of thinking.

Johnson's political ideas, which apart from a few pamphlets written at the request of the government appear mostly in the form of *obiter dicta*, are those of a strong eighteenth century Tory but are too individual to be regarded as typical. His devotion to the monarchy was fundamentally emotional, but his belief in the absolute power of sovereignty was reasoned. "There must in every society be some power or other from which there is no appeal." This was to him a matter of fact; but it was equally true that if the government abused its position too much the people would rebel. Johnson's objection to the American Revolution (as seen especially in *Taxation No Tyranny*, 1775) was not entirely mere prejudice; it arose also partly because the revolution did not appear to him to be based on such practical grievances as alone might explain—one can hardly say justify—rebellion and partly because any claim founded on principles of equality could not be put forward, he thought, on behalf of a slave owning society. Although he abused Rousseau, Johnson had a certain belief in the natural rights of man which made him an early and uncompromising enemy to slavery. Similarly, although devoted to the Church of England he criticized severely the intolerance of the English government in Ireland. In economic matters he took little interest, his sole work of the slightest importance in this field being a tract entitled *Considerations on the Corn Laws* (1766, first published in W. G. Hamilton's *Parliamentary Logick*, London 1808). This defends the export bounty on corn on the ground that by stimulating production it lowers the price and decreases the risk of famine. A believer in the rule of the landed proprietage, he insisted on its responsibilities and approved, for instance, the English system of poor laws. His nature was fundamentally religious and his conservatism at bottom a belief that man being naturally rebellious requires the control provided by custom and strong government.

ALFRED COBBAN

Works: In addition to his literary works Samuel Johnson wrote the following political pamphlets: *The False Alarm* (London 1770); *Thoughts on the Late*

Transactions respecting Falkland's Islands (London 1771); *The Patriot* (London 1774); *Taxation No Tyranny* (London 1775).

(Oxford 1887); Stephen, Leslie, *Samuel Johnson*, English Men of Letters series (London 1878), and *History of English Thought in the Eighteenth Century*, 2 vols. (3rd ed. London 1902) vol. ii, p. 206-09, 374-76; O'Brien, George, "Dr. Samuel Johnson as an Economist" in *Studies* (Dublin), vol. xiv (1925) 80-101; Harvey, C. W., "Johnson's Hatred of America" in *Cornhill Magazine*, n.s., vol. lxvii (1929) 655-68.

JOHNSON, TOM LOFTIN (1854-1911), American municipal reformer. Johnson acquired a substantial fortune in his early twenties through his inventions and his skill in managing street car properties; he later obtained traction interests in Indianapolis, Cleveland, Detroit and Brooklyn, as well as iron manufactures in Ohio and Pennsylvania. Through a casual reading of *Social Problems* he became a convert to the doctrines of Henry George. Convinced of the injustice of a society which permitted large fortunes like his own to be acquired through monopolistic practises, Johnson determined by political action to strike a blow at monopoly. After one defeat he was elected to Congress as a free trade, single tax Democrat and served two terms in the House of Representatives (1891-95).

A convinced believer in decentralized government and direct democracy, he conceived the city to be the most promising field of political activity. He sold his railroad properties and in 1901 was elected mayor of Cleveland on a public ownership, three-cent fare platform. He was three times reelected but encountered strong opposition to his plans for cheap traction. A settlement achieved in 1908 was repudiated by a narrow majority in a referendum; lowered earnings, an economic depression and a strike had destroyed public confidence in his traction policy. However, the three-cent fare he had established remained in effect for a time under the privately owned company.

Johnson's administration was also distinguished by improvements in parks and playgrounds, municipal sanitation and city purchasing and by the establishment of farm colonies for defectives and delinquents and group planning for city building. He was described by a co-worker as "the greatest administrator, the most efficient executive that the radical movement has produced in this country." He brought into public life such leaders as Newton D. Baker, John N. Stockwell, W. B. Colver, Edward W. Bemis and Frederic C. Howe. Johnson's most

notable achievement was the creation of a civic spirit in Cleveland which stimulated the municipal reform movement throughout the country.

JOHNSTON, SIR HARRY HAMILTON (1858-1927), British colonial administrator and ethnographer. Johnston's career provides an outstanding example of the mingling of scientific curiosity with imperialistic and administrative ardor in the "scramble for Africa." After engaging in explorations in Angola and along Stanley's Congo trail Johnston in 1884 led an expedition to Mount Kilimanjaro; this expedition, scientific in its nature, masked the negotiation of numerous treaties and concessions with native princes, some of which became the basis of British rule in Kenya. An article in the London *Times* of August 22, 1888, in which he outlined the course which British expansion was to attempt to follow in Africa, including the "Cape to Cairo" idea, was the sequel to a discussion with Lord Salisbury. Johnston began his administrative and consular career in the Cameroons in 1885. From 1889 to 1896 he was engaged in the acquisition and administration of the Nyasaland protectorate, aided financially by Cecil Rhodes, for whom he also administered other territories within this period. From 1899 to 1901 he undertook the definite organization of the Uganda protectorate. His last African mission, undertaken on behalf of British rubber interests in Liberia, was unsuccessful in its objects, although Johnston aided the establishment there of an American financial protectorate. His administrative policies emphasized watchful cooperation with other colonial powers, free trade, the suppression of the slave traffic, neutrality toward missionary enterprise and marked sympathy for native institutions, with the partial exception of communal land tenures. In large volumes he collated the data of the physical and economic geography, biology, physical anthropology, ethnography and linguistics of the regions in which he served. He wrote voluminously upon the history and problems of expansion and of the contacts of white and colored races, including the American Negro question. He maintained that the so-called backward peoples benefited by these contacts in so far as they implied gradual assimila-

tion of European culture under benevolent white mastery. His outstanding work is the *Comparative Study of the Bantu and Semi-Bantu Languages* (2 vols., Oxford 1919-22), a compendium of contemporary knowledge of the subject. Although his formal and theoretical training was limited, art studies and a freedom from theological preconceptions brought acuteness and objectivity to Johnston's observations.

JOINT COST. *See* COST; OVERHEAD COSTS.

JOINT STOCK COMPANY. The phrase joint stock company is capable of various interpretations. Interpreted broadly it signifies a company or group of persons associating in the provision of a fund of goods or money to undertake some common business enterprise. It is, however, more commonly interpreted to include only associations of persons providing a joint stock and pursuing a common enterprise, membership in which is evidenced by transferable shares.

The earliest English trading corporations, the "regulated" or "open" companies, such as the Merchant Adventurers, do not fall within this definition. As corporations they held exclusive trading rights and possessed a common purse which was employed for collective defense, the maintenance of ambassadors and the charitable assistance of members. But the members traded on their own behalf and supposedly in competition with each other. Groups of members did, however, cooperate to trade with a joint stock and in the sixteenth century the ideas of the incorporated company and of joint stock trading were united in the incorporation of the Muscovy, Levant, East India and other companies, all of

which possessed exclusive trading privileges. The device of permanent stock freely transferable developed but slowly during the succeeding century. Toward the end of the seventeenth century the speculative possibilities of transferable stocks and the profitability of company promotion greatly stimulated the formation of unincorporated associations, called companies but regarded at law as partnerships and possessing no exclusive trading privileges. Their inability to sue or to be sued except in the names of all their members as well as the unlimited liability of their members gave rise to confusion, and the frenzied speculation in the shares of such companies during the early years of the eighteenth century resulted in the Bubble Act of 1719 prohibiting the formation of joint stock companies except by royal charter. The act was never effective, largely because of its unintelligibility, and when it was repealed in 1825 the aggregate capital of the unincorporated companies in existence was estimated at between £160,000,000 and £200,000,000. The statute then passed amended the common law to permit the chartering of companies without endowing them with unlimited liability; unchartered companies remained subject to the common law, the provisions of which with regard to such companies were still far from clear. In 1834 authority was given to endow them by letters patent with the right to sue and to be sued in their own names; in 1844 provision was made for registration and incorporation without limitation upon liability, the latter privilege being finally granted in 1855. Since 1862 it has been illegal to form any new company, association or partnership consisting of more than twenty persons (ten if engaged in banking) for the acquisition of gain without registering the formation under the companies acts (unless the company is regulated by special statute or protected by letters patent). As all companies registered are incorporated, the unincorporated joint stock company no longer exists in England. Not all incorporated companies, however, are strictly joint stock companies: companies are incorporated which are "limited by guarantee" and such companies need have no capital stock. Nor do all incorporated companies enjoy limited liability: provision is made for incorporation with unlimited liability. Incorporated associations which would in America be called corporations are commonly referred to in England as joint stock companies or more loosely and less accurately as limited companies.

In the United States the common law right to

form unincorporated joint stock companies has never been withdrawn by statute and the term joint stock company has a technical meaning differentiating such common law associations from partnerships on the one hand and corporations on the other. Such a company is defined as an unincorporated partnership with a capital divided into shares (not necessarily all of one class) which are freely transferable, and ownership of at least one of which is essential to membership in the company. Relations between the members are regulated by a contract (the articles of association), which brings the association into being without any charter or grant by the state, except in jurisdictions where the common law has been modified by statute. A number of states, including Michigan, New Jersey, New York, Ohio, Pennsylvania and Virginia, have imposed varying degrees of statutory control, equivalent in some to the control exercised over corporations. Elsewhere joint stock companies pay no franchise tax and make no report to any public officer upon their formation or their transactions. In law such companies resemble corporations only in that they possess sufficient continuity of existence apart from their members for the withdrawal of a member not to terminate the existence of the company. In practice, however, they resemble corporations in that active control is exercised by a board of directors elected by the members (who have no power to contract on behalf of the company). The company cannot sue or be sued in its own name, although in many jurisdictions it may—in some it must—be sued through its officers in the first instance. It is incapable of holding real estate, which is usually vested in trustees appointed for the purpose. The members are jointly and severally responsible without limit for the debts of the company unless every contract provides that the property of the company alone shall be bound. The joint stock company is not now a common form of business organization, partly on account of the liability of members for all the debts of the company and partly on account of the greater convenience of the corporation (*q.v.*), facilities for the formation of which have been rapidly extended since the removal in the early nineteenth century of the necessity of special legislation to secure incorporation.

The development of the limited partnership in many jurisdictions has given rise to a form of organization allied to the joint stock company. Partnership in which the liability of some partners for the debts of the group is limited (such

partners usually having only restricted rights to participate in management) is permitted in France, where it is known as a *société en commandite*; in Germany, where it is known as a *Kommanditgesellschaft*; in England and in most American states. In both France and Germany, however, the rights of the members whose liability is limited may be represented by shares similar in all respects to those issued by corporations. Such a *société en commandite par actions* in France or *Kommanditgesellschaft auf Aktien* in Germany resembles a corporation at least one of whose members is responsible without limit for the debts of the corporation. In Pennsylvania and Michigan provision is made for quasi-corporations known as partnership associations, the liability of all the members of which is limited and which may issue stock certificates representing the interests of the partners; the certificates are, however, not freely transferable and members have the right to refuse to accept any transferee as a member.

Special facilities have also been provided since 1892 in Germany and since 1900 in England for the further extension of the privilege of incorporation with limited liability to firms owned by a relatively small number of persons desirous of avoiding the publicity and regulation imposed upon corporations. Both the *Gesellschaft mit beschränkter Haftung* (G.M.B.H.) in Germany and the private company in England have a capital divided into shares. The shares of the former are not negotiable, the company having the right to control their transfer. The transfer of the shares of the private company must always be restricted. It may not invite public subscription to issues of shares or bonds nor may it permit the number of its stockholders to exceed fifty (subject to exceptions arising out of employee stock ownership) or to fall below two. The G.M.B.H. although intended for small enterprises has been more widely used than was anticipated, and many of the largest and best known German enterprises are organized in this form.

The most evident consequence of the employment of the principle of joint stock is the development of enterprises of enormous size under single control. In the sixteenth and seventeenth centuries, however, the opportunities it offered for the distribution of risk appear to have been more important. Political incapacity to provide for the security of property and the difficulties of transportation attached considerable risk to trade with distant parts; these risks were diminished by the establishment of large companies capable

of providing for the defense of their property and were more widely spread by the inclusion of a number of voyage risks within a single account and the facilitation of membership in a number of companies. The opportunities for fraud offered by the divorce of the control of property from its ownership in the joint stock company were first exploited on a large scale in the early years of the eighteenth century. Although two joint stock companies were incorporated in England in 1568 to engage in mining, it was not until the nineteenth century that changes in the technique of production involving division of labor and the employment of durable equipment upon a scale larger than ever before stimulated the general application of the principle of joint stock first to canals and railroads and later to manufacturing. The rapid and progressive increase in the size of corporate units gives rise to serious questions concerning the consequences of the increasingly wide separation of ownership from control and the progressive concentration of control. Theoretical analysis of these consequences has made little progress, and, partly in consequence, the problem of the proper policy of social control remains unsolved.

JOLY, CLAUDE (1607-1700), French political theorist. Joly first became a lawyer but at the age of twenty-four took orders and was later appointed canon of Notre Dame in Paris. He accompanied the duke of Longueville to the Congress of Münster and retired to Rome during the *Fronde*.

Joly's writings are characteristic of the intellectual unrest which marked the troubled period of the *Fronde* and which inspired the many timely political pamphlets known as *Mazarinades*. Among them his pamphlets stand out because of their synthetic and philosophic treatment of the problems of government. His most significant work is the *Recueil . . .*, which was condemned by the tribunal of the Châtelet. Joly maintained that this work was by no means factional but on the contrary conformed to traditional French political principles. Opposed to despotism, he declared that the people had actually instituted the kingship and that consequently kings derived their authority from them. This theory he attempted to reconcile by rather subtle arguments with the principle of the divine right of kings.

Since the royal power is derived and is therefore not unlimited, as self-interested counselors pretend, sovereigns cannot infringe upon certain individual rights specifically reserved to the people by a sort of pact between rulers and their individual subjects. Of these rights, Joly pronounced himself vigorously in favor of liberty of the press and of religious toleration as formulated by the Edict of Nantes. Moreover kings have no authority to impose taxes without the consent of their subjects. Fortifying his position with examples from history Joly held that every new tax should be submitted to the Estates General or in lieu of this institution to the *parlement*, which he believed had issued from it. The king moreover cannot undertake war without consulting his subjects. The people may also demand the dismissal of incompetent ministers—a statement which evidently alludes to Mazarin.

Joly offers few precise ideas for the practical reform of administration. He showed some hostility toward the institutions of the intendant and the governor and stressed the vexatious abuses of power by the military. On the religious question he favored the liberties of the Gallican church. Joly considered himself quite the opposite of revolutionary; nevertheless, as an adversary of the absolutist principles which triumphed under Louis XIV he is a precursor of the liberal writers of the eighteenth century.

JONES, ABSALOM (1746-1818), American Negro religious organizer. In 1762 Jones, who was born a slave in Sussex, Delaware, came with his master to Philadelphia, where he was permitted to enter night school. In 1784 he was granted his freedom, but he continued to work for his former master and accumulated property of considerable value.

The Negro worshipers in St. George's Methodist Episcopal Church in Philadelphia, humiliated by the treatment accorded them, withdrew in 1787 under the leadership of Jones and Richard Allen and formed the Free African Society. The objects of the organization, which represents the first attempt in the United States at group organization by the Negro people, were the exercise of discipline over the personal lives of its members and the extension of mutual aid in the time of distress without regard to religious tenets. Divisions arose within the organization over religious attachments. Allen decided to establish the African Methodist Episcopal church, of which he became the first bishop. Jones sympathized with Allen but finally yielded to the opinion of the majority and affiliated with the Protestant Episcopal church. In 1791 the society changed its name to the Elders and Deacons of the African Church and in 1794 to the St. Thomas African Episcopal Church of Philadelphia. Jones was ordained to the priesthood in 1804; he was the first Negro priest of this denomination in the United States.

In 1793, when an epidemic spread throughout Philadelphia, Jones and Allen took the leadership in the organization of relief measures for the Negro population and later published an account of these efforts. Jones also founded and operated an insurance company, organized a society for the suppression of vice and immorality and with Allen and James Forten raised a brigade of 3000 Negro soldiers for the War of 1812.

JONES, ERNEST CHARLES (1819-69), English politician. After a youth passed in aristocratic circles in Germany and England, Ernest Jones became a barrister and litterateur. An early tendency toward radicalism increased until he became in 1846 a leader of the Chartist movement, then approaching its final stage. As member of the Fraternal Democrats, an association largely composed of foreign refugees, he helped impart to Chartism an international outlook. While Jones made no important contribution to socialist thought, his leadership of the Chartist movement was characterized by a spirit of militant socialism which was intensified by direct contact with Karl Marx in the early 1850's. His newspapers, *Notes to the People* (1851-52) and the *People's Paper* (1852-58), propagated Marxian doctrines, especially that of the class struggle; and Engels said in 1869 that Jones was the only prominent English politician who thoroughly understood the socialist movement.

Failing to win over the mass of workers to a class struggle position, he adopted the program of a middle class political alliance. In 1858 he formed a manhood suffrage association of both classes which helped launch the movement that secured the franchise for urban workers in 1867. Throughout the agitation Jones was the uncompromising advocate of democracy and was the chief bridge between Chartism and working class radicalism. In the election of 1868 his strength with labor electors forced the Liberals to accept him as a candidate for Manchester; although he was defeated he received a large vote.

JONES, LLOYD (1811-86), British cooperator. A skilled tailor and trade unionist, Jones was converted to Owenite socialism in his twenties. His attitude to the labor movement was largely determined by the view that the central problem was "the relation of the workman to his work." As an Owenite missionary upholding the principle of "reason" he frequently clashed with Chartist leaders. Although indifferent to religion

he was attracted by those elements in Christian Socialism which stressed cooperative production and the importance of social as distinct from political evils, and he brought to this movement not only exceptional gifts of tongue and pen but a wide knowledge of the labor movement.

While he approved of arbitration and acted as union advocate in arbitration proceedings he opposed sliding scales and held that the overstocking of a market should be met not by reducing wages but by restricting supply. The maintenance of wage levels alone left untouched the social evils arising from the divorce of the workman from his work, and Jones asserted that to deal with these wider problems cooperation was necessary.

He was active in federating retail cooperative societies. He approved of the cooperative dividend and held that the main question of distributive cooperation was whether the shareholders would be willing to share profits with the workmen instead of treating them as mere "hands" and, if they did, whether they could make their capital remunerative in a competitive world. Distributive cooperation had, he said, broken down in generosity on this crucial point.

JONES, MARY (Mother) (1830-1930), American labor agitator. Mother Jones was born in Ireland of a working class family and came to America when she was six years old. After a series of misfortunes which left her destitute she was inspired by the Knights of Labor movement to become a crusader in behalf of American labor. In 1873 she took part in the strike of the Baltimore and Ohio Railroad employees and from that year until her death was actively associated with the labor struggle. For years she appeared in most of the major strikes, often by invitation of the leaders but many times by her ability to insinuate herself into a lead. She did most of her work among the miners, with whose union she remained closely associated all her life, and her work was particularly effective in West Virginia and Colorado, where as a result

of her complete fearlessness she was frequently in jail.

Essentially she was a revolutionist, although she never fully analyzed her own program or adopted any one revolutionary philosophy. She participated as effectively in strikes of the Industrial Workers of the World and other revolutionary bodies as in those of the ultraconservative unions of the American Federation of Labor, but from every platform she urged the workers to destroy capitalist society. She had no sympathy with woman suffrage or any other woman's movement, but she urged women to play their part in the class struggle and organized them into brigades for all strikes. Child labor was particularly abhorrent to her, arousing her to her most spectacular activities.

In the union office she was out of place, quarreling with officials, offering no constructive policy of her own and constantly violating union policy. It was in the field that she made her real contribution. With one speech she often threw a whole community on strike and she could keep the strikers loyal month after month on empty stomachs and behind prison bars. By virtue of her outstanding personality, intrepid daring and complete devotion to their cause Mother Jones captured the imagination of the American workers as no other woman has yet done.

TOM TIPPETT

Consult: *Autobiography of Mother Jones*, ed. by M. F. Parton (Chicago 1925).

JONES, RICHARD (1790-1855), English economist, cleric and administrator. Jones, who was educated at Cambridge, became professor of political economy at King's College, London, in 1833 and two years later succeeded Malthus at East India College, Haileybury, where he continued to teach until shortly before his death. Between 1836 and 1851 as a commissioner of tithes he played an important part in administering the act providing for the commutation of tithes, publishing various pamphlets on the subject; after 1851 he was active in other administrative capacities.

At a time when the Ricardian approach dominated English economic thought Jones asserted the claims of the historical method, stressed the significance of statistics and emphasized the influence of past experience and social institutions upon human behavior. He is best known for his attack upon the Ricardian theory of rent. He claimed that the pessimistic conclusion that rents could increase only at the expense of other in-

comes arose out of a confusion between proportions and absolute amounts and that the Ricardian assumption of diminishing returns ignored the inventive capacity of man and the effect upon production of increasing investment in capital equipment. Attributing Ricardo's theory to a too exclusive attention to English institutions he attempted to demonstrate by a comparative study of systems of land tenure the variety of influences determining rent. The first part of his *An Essay on the Distribution of Wealth and the Sources of Taxation* (London 1831) has been republished under the title *Peasant Rents* (London 1895). While his failure adequately to appreciate the concept of differential rent exposed him to attack, his emphasis upon property laws as a determinant of distribution has now been accepted by economists. Approaching the theory of production from the same standpoint he emphasized the influence of institutional factors in determining the reaction of the labor force to an increase in remuneration, advancing thereby powerful arguments against the contemporary view that increases in wages almost inevitably stimulate population growth. His analysis of the influences affecting the accumulation of capital, wherein he again took issue with Ricardo, was later elaborated by Sidgwick and Cannan.

Despite its freshness of approach the relatively minor influence of Jones' work must be attributed in part to the entrenched position of the Ricardian group but perhaps even more to the pressure of his teaching and administrative duties and to his disinclination to writing. He published no comprehensive and systematic development of his ideas; his lectures, occasional essays and comments were published after his death, together with a sympathetic memoir, by his admirer William Whewell as *Literary Remains* (London 1859). Despite repetition and lack of order they reveal an original and occasionally brilliant mind.

JONESCU, TAKE. *See* IONESCU, TAKE.

JORDAN, DAVID STARR (1851-1931), American naturalist, educator and social philosopher. Jordan's contributions in various fields of natural science, notably in ichthyology, were reflections of his underlying interest in the relation

of the species to environment. In a number of works written between 1902 and 1915 he developed the concept of the devastating effects of war on the human species. Although this hypothesis had been anticipated by Darwin in 1871 and developed by Novikov in 1894, Jordan was the first to give it thorough scientific support. His thesis that war by reverse selection leaves the weaker and less heroic to perpetuate the race was not universally accepted by authorities but furnished effective ammunition against popular social Darwinism. Jordan's researches and reflections confirmed his faith in democracy as the necessary condition of world peace. While rejecting socialism he insisted that profits must be eliminated from the war system. Just as he desired the students at Leland Stanford University, which he organized in 1891 and of which he was president and later president emeritus, to have the greatest freedom of choice after all the facts had been presented to them, so he wished to promote peace by an enlightened public opinion. As a lecturer at home and abroad, as a director of the World Peace Foundation and as the recipient of the Raphael Herman Award he turned the attention of the peace movement toward fact finding techniques. His consistent and at times heroic work for international peace gives him a permanent place in the history of the effort to apply science to social problems.

JÖRG, JOSEPH EDMUND (1819-1901), Bavarian politician and Catholic publicist. Jörg served as assistant to Dollinger while engaged in historical studies which resulted in the publication of his *Deutschland in der Revolutions-Periode von 1522 bis 1526* (Freiburg i. Br. 1851). In 1852 he took over the direction of the *Historisch-politische Blätter* founded by Görres. From 1865 to 1881 he was a member of the Bavarian chamber, from 1874 to 1879 of the German Reichstag. He played a prominent role in Bavarian politics as leader of the patriotic People's party, which in 1869 secured the ma-

jority and brought about the fall of the liberal premier Hohenlohe. The party did not follow his lead, however, when in 1870 he opposed participation in the war with France and demanded an armed neutrality for Bavaria. He was likewise deserted by the party in 1871 when he repudiated the Versailles treaties for the foundation of the empire, which appeared to him an insufficient guaranty of the rights of Bavaria.

Jörg's basic political and social position was anti-Prussian and antiliberal. He had originally hoped that by agreement with Prussia there would be formed a Christian-German *Mitteleuropa* under Austrian-Hapsburg leadership, in which Bavaria could have a strong position. In the unification of Germany under Prussian leadership through the policies of Bismarck he saw a threat to the independence of Bavaria, a mediocrization of all states by the house of Hohenzollern. Prussia appeared to him as a Protestant power and as the representative of a centralization directed against historical development and the cultivation of local peculiarities. Jörg's antiliberalism is displayed in a sharp critique of liberal economics. In his *Geschichte der sozial-politischen Parteien in Deutschland* (Freiburg i. Br. 1867) he welcomed the labor movement promoted by Lassalle, since it was directed against bourgeois liberalism, but definitely rejected Lassalle's general *Weltanschauung*. A healthy social reform, which preserves itself from excessive industrialism and consequent pauperism, he held, is possible only for a Christian society. Bismarck's socio-political legislation based on the state was contemptuously characterized by Jörg as centralistic and unmindful of the organic construction of society.

Jörg was gradually forgotten in the Catholic movement of Germany. No connection was possible between his position and the political and social evolution in which the Catholics in the Center party were cooperating through affirmation of the existing state and prominent participation in the construction of socio-political legislation. Only in late years since the crisis of 1918 in Bismarck's empire has there been a noticeable revival of interest in Jörg, especially in his unsystematically formulated critique of liberal economics interpreted as an actual critique of capitalism.

WALDEMAR GURIAN

Consult: Wöhler, Fritz, *Joseph Edmund Jörg und die sozialpolitischen Richtungen im deutschen Katholizismus* (Leipzig 1929), with an extensive bibliography.

JOSEPH II (1741-90), Holy Roman emperor. Joseph II represents the purest type of enlightened despot. Even while coregent with his mother, Maria Theresa, he sought to put into practise the new concept of the state which he had learned from the example of Frederick the Great, from Voltaire and from the French *encyclopédistes* and physiocrats. The monarch must be the first servant of the state and devote himself to the welfare of the people. But in order to be able to fulfil his duties he must be absolutely sovereign; he must not be bound by either statute or privilege, by church authority or by ancient law and custom. It is incorrect to consider Joseph II as the forerunner of modern democracy and equally so to see in him only a violent absolutist. His significance lies in the fact that he tried to combine the idea of the welfare state with that of the authoritarian state.

His foreign policy was imperialistic. He favored the partition of Poland in 1772, took Bukovina from Turkey in 1775, helped incite the war of Bavarian succession in 1778 in order to put the house of Austria in possession of lower Bavaria, pursued the scheme of a Hapsburg-Wittelsbach exchange of territories (the Netherlands for Bavaria) in 1785, concluded an alliance with Catherine II against the Porte in 1781 and played with the idea of a division of the world between Austria and Russia with Rome and Constantinople as the capitals. In his rule of the empire he revived the centralistic imperial policy of Charles V and Ferdinand II, reformed the decadent High Court of Justice in Vienna and endeavored to break the power of the German princes.

In his internal policy also Joseph endeavored primarily to strengthen and increase the national potentiality. He created new administrative districts, placed in the cities magistrates appointed by the throne, instituted paid judges and new rules of judicial procedure. He forcibly united the various states in Austrian territory, making German the official language in Hungary in 1784. This emphasis of state authority led necessarily to conflict with the church. In place of an ultramontane church Joseph wished to institute an Austrian national church and to bring it securely under the control of the emperor. "Josephinism" is accordingly an exact parallel to the Gallicanism of the French kings. The state was to educate the priests, manage the church's patrimony, regulate the forms of service and through its placet allow or deny church ordinances. Contact between the religious orders and

the generals of the orders outside Austria was forbidden. Marriage was removed from the church's jurisdiction and considered a purely civil contract.

Even his ecclesiastical policy was guided by his concept of the welfare state. Religion was judged according to its civil utility: of the two thousand monasteries a third were abolished by the law of 1781 since they served only asceticism and represented therefore "dead human capital"; the Protestants, Greek Catholics and Jews were granted toleration by the Patent of Tolerance, 1781, because they were farmers and workmen performing necessary functions. The humane views of the Enlightenment bore fruit in all possible fields. Joseph introduced general compulsory schooling; he built the first national hospitals, founding homes and insane asylums, thus becoming known as "the good Samaritan on the throne"; he did away with torture and trials for witchcraft, punished dueling and exercised a very tolerant censorship. More important was the struggle against the aristocracy and the abolition of the serfdom of the peasants, who moreover were thenceforth to remain on their property not as owners but as free copyholders. If the new land taxes which Joseph had planned had been preserved after his death they would have altered the entire social structure of Austria by virtue of the heavy burden they placed on the estates of the nobility. His reforms, however, were without permanent results. After ten years of illustrious but precipitate rule Joseph, the public benefactor, lived to see revolution break out against him in Belgium and Hungary because of his disregard for the old constitutional privileges of Brabant and for the national autonomy of Hungary.

JOSEPHUS, FLAVIUS (Joseph ben Matthias) (c. 37-c. 100 A.D.), Jewish historian. Josephus was a scion of the high priests of Judea. He spent two years, 64 and 65, in Rome moving in circles close to the emperor Nero and became imbued with a very strong faith in the power of the sovereignty of the Roman Empire. Moved by Jewish patriotism, however, he joined for a brief period the insurrection in Judea in 66 and commanded the insurgents in Galilee. But the first attacks by the Roman army convinced him of the utter uselessness of the struggle of a small country against the world empire and he left his own people, joined the camp of the Roman chief Vespasian and during the siege of Jerusalem assumed the role of mediator between the two fighting armies. After the destruction of Jerusalem and the devastation of Judea (70-73) Josephus went to Rome in the retinue of the conquerors and lived thereafter at the court of the emperors Vespasian and Titus. Here he wrote in Greek his remarkable historical works, which are among the foremost masterpieces of ancient rhetorical historiography.

In his first important work, *The Jewish War*, Josephus recounted the cruelties of the Roman procurators in Judea which had driven the people to revolt and told of his own participation in the defense of Galilee. He placed the entire responsibility for the struggle and the subsequent destruction of Judea, however, upon the party of fanatical Judean Zealots, who continued to fight Rome even after it had become evident that the struggle was doomed. His work was apparently inspired by the Roman conquerors and was intended to serve as a warning to other peoples in the East against opposition and revolt. In his *Jewish Antiquities*, motivated by the desire to magnify Jewish civilization in the eyes of the Gentile world, Josephus attained the level of a historiographer of national scope in linking his own epoch to the remote period of the rise of the Jewish people. In his rhetorical fashion he recounts the contents of the historical books of the Bible and on the basis of Greek sources which have not survived and from the Apocryphal books, *Maccabees*, he describes the Greek domination in Judea, the independent reign of the Hasmonaeans, the reign of Herod and the Roman rule down to the last procurators. In spite of all the characteristic shortcomings of his historiographical method the presentation of the post-Biblical epochs in the two works of Josephus are of tremendous significance for the political and social history not only of Judea but of the

Graeco-Roman world in general. Josephus has saved from oblivion an extensive period in Jewish history and the sources pertinent to it. His works constitute a direct but more secularized continuation of the historical books of the Bible and of the Apocrypha. His autobiography is also of some social-historical interest as well as his apology for Judaism, *Against Apion*, in which he cites all examples of Judophobia in antiquity, particularly in the Jewish-Hellenic metropolis of Alexandria.

Works: *Opera*, ed. by Benedict Niese, 7 vols. (Berlin 1885-95); *Oeuvres complètes de Flavius Josephus*, tr. by Théodore Reinach, J. Weill, and J. Chamonard, vols. i-v, vii (Paris 1900-29); *Josephus*, original Greek text and translation by H. St. J. Thackeray, Loeb Classical Library, vols. i-iv (London 1926-30). The first part of the Slavic Josephus has been translated into German by Alexander Berendts and Konrad Grass, *Vom jüdischen Kriege, Buch I-IV, nach der slavischen Übersetzung*, 2 vols. (Dorpat 1924-27).

Consult: Thackeray, H. St. John, *Josephus, the Man and the Historian* (New York 1929); Laqueur, R. A., *Der jüdische Historiker Flavius Josephus* (Giessen 1920); Foakes Jackson, F. J., *Josephus and the Jews* (London 1930); Niese, Benedict, "Der jüdische Historiker Josephus" in *Historische Zeitschrift*, vol. lxxvi (1896) 193-237; Schürer, Emil, *Geschichte des jüdischen Volkes im Zeitalter Jesu Christi*, 4 vols. (4th ed. Leipsic 1901-11), tr. by Sophia Taylor and Peter Christie, 5 vols. (2nd ed. Edinburgh 1886-90) vol. i, p. 77-110. For the problem of the Slavic Josephus see Eisler, Robert, *Ἰησοῦς Βασιλεὺς οἱ Βασιλεύσας: Die messianische Unabhängigkeitsbewegung vom Auftreten Johannes des Täufers bis zum Untergang Jakobs des Gerechten . . .*, 2 vols. (Heidelberg 1929-30), partly tr. by A. H. Krappe as *The Messiah Jesus and John the Baptist* (London 1931).

JOST, ISAAC MARCUS (1793-1860), Jewish historian. Jost was born at Bernburg in Anhalt and after attending the Samsonschule at Wolfenbüttel he continued his studies at the universities of Berlin and Göttingen. He was principal of a private *Gymnasium* from 1825 to 1834 and passed the rest of his life as teacher at the Jewish Philanthropin in Frankfurt on the Main. For two years from 1839 to 1841 he edited the *Israelitische Annalen* for the purpose of collecting materials for Jewish history.

Jost is deservedly called the father of Jewish historiography. With no predecessors except the Frenchman Basnage, whose compilation he utilized, he collected and worked over the various sources of Jewish history. A rationalist, Jost displays not the slightest throb of romantic exaltation in his discussion of even the most martyr crowded eras of Jewish history. His rationalist

convictions, however, did not prevent him from being conservative in his analysis of sources, particularly those of the Biblical epoch. Although he held the view that the Talmud was the cause of Jewish misfortunes he appraised this collective creation of the Jewish people as an important historical source. A skeptic by nature, he still defended the "good will" of the Christian rulers and kings toward the Jews in the period of their exile. The most important part of his historical work, all of which retains its full value as a historical source, is the section in which he deals with his own epoch, the years 1815 to 1846. The parts dealing with the Jewish settlements in Germany in the Middle Ages are also of pioneer significance.

Jost made no contributions to historical methodology and he did not evince the analytical keenness characteristic of Graetz. His style is dry, his descriptions devoid of animation and fantasy; but for a long period his works were the only sources from which the Christian world drew its information concerning Judaism and the Jews. In his social and religious beliefs Jost was a moderate assimilationist and a supporter of the moderate reform movement.

JACOB SHATZKY

Important works: *Geschichte der Israeliten seit der Zeit der Maccabäer bis auf unsere Tage*, 10 vols. (Berlin 1820-47); *Geschichte des Judenthums und seiner Sekten*, 3 vols. (Leipsic 1857-59).

Consult: Baron, S., "I. M. Jost the Historian" in *American Academy for Jewish Research, Proceedings* (1928-30) 7-32; Meisl, Josef, "Die jüdische Geschichtsschreibung" in *Jude*, vol. vi (1921-22) 283-96; Zirndorf, H., *Isaac Markus Jost und seine Freunde* (Cincinnati 1886).

JOURDAN, ALFRED (1823-91), French economist. Jourdan was one of the small group of twelve professors appointed to teach political economy in the faculties of law in France when the subject was introduced in 1878. Apart from a mediocre work, *Épargne et capital* (Aix 1879), which is overloaded with moral and philosophical considerations and fails to achieve an exact analysis of the concept of capital, Jourdan left behind him two works on economics which are still read with interest. In *Du rôle de l'état dans l'ordre économique* (Paris 1882), crowned by the Institut de France in 1882, he develops the doctrine of individualism while avoiding the exaggerations of the orthodox school. A study of history, the laboratory of the social sciences, led Jourdan to conclude that the development of civilization is marked by a steady decline in state

regulation of economic activity. But at the same time that the state was abandoning direct economic paternalism it was engaging to an increasing degree in the task of providing the social facilities prerequisite to economic development, such as educational opportunities and social legislation. This double, parallel evolution expresses the law of progress. The recognition of this law led Jourdan to reject the extreme solutions of both socialism and uncompromising *anti-étatisme* and formulate the theory of moderate individualism. This "true" liberalism is notable for the support which it provided for the foundation of the *Revue d'économie politique* in 1887. Not allowing himself to be intimidated by the violent hostility of orthodox quarters, Jourdan accepted a post on the directing committee, where he represented, with Edmond Villey, the individualistic tendency, while Charles Gide and Léon Duguit supplied the note of interventionism and solidarism. In *Des rapports entre le droit et l'économie politique* (Paris 1885) Jourdan stressed the close relation of law and economics and argued that the two may be legitimately included in the same educational institutions.

JOURNALISM is one of the younger professions. Courants, gazettes and newsbooks flourished in England and on the continent in the second quarter of the seventeenth century and there were more than twenty English newspapers by the time of the Restoration, but until the latter part of the eighteenth century journalism remained rather a business or an adjunct of politics than a true profession. Only in a very loose sense are journalists justified in regarding Addison and Steele, Defoe, Swift (who edited the *Examiner* in 1710), Franklin and Marmontel as early figures in their profession. Addison and Steele, Swift and Marmontel were men of letters, Defoe was a pamphleteer and Franklin was a versatile business man. Assuming that a profession deserves the name only when it stands alone, requires a distinctive training, employs men for a lifetime of single minded endeavor and has a fixed set of non-commercial standards and aims, the profession of journalism was scarcely born until after 1760. Between then and 1800 there were in both Europe and

America a small but steadily increasing number of journalists who were something more than printers, party hacks or literary men temporarily using a newspaper or magazine as a mouthpiece. By 1776 there were well established and important newspapers in Germany (the *Frankfurter Postzeitung*, *Vossische Zeitung*, *Hamburgischer Correspondent* and others) and in France (the *Gazette de France*, the *Mercure de France*), fifty-three newspapers were published in London and the American colonies had thirty-seven—a firm basis for development.

Beginning with 1760 or 1770, four stages may be marked in the professional evolution of journalism. The first was the achievement of that degree of freedom of speech which is essential to enterprise, dignity and independence. In the United States the revolution completely unfettered the press; in England the battles of John Wilkes and Henry S. Woodfall for journalistic liberty, the establishment in 1771 of the right to print parliamentary proceedings and the passage in 1792 of Fox' Libel Act did almost as much; and on the continent the French Revolution had liberating effects. The second stage was the emergence of the press from party subserviency to a broad appeal to the reading public. Until after 1815 the most important newspapers in Europe and the United States, apart from commercial gazettes, were supported by political groups. The ablest American editors, Philip Freneau and William Coleman, were set up by Jefferson and Hamilton respectively; the London *Public Advertiser*, in which the "Letters of Junius" appeared, the *North Briton* and the *Morning Post*, in which Coleridge's articles were said to have led to the rupture of the Treaty of Amiens, were all party organs; and in France Condorcet, Mirabeau and Brissot de Warville brought politics and journalism into the closest union. The divorce of the press from a servile dependence upon party took place first in the English speaking countries. It was achieved partly through political changes; partly by broadening the basis of newspaper support, the penny press of London about 1830 and of New York a few years later showing that the masses might be reached; and above all by an immense development of general news gathering at the expense of political articles. The enterprise of the Walter family in England and of James Gordon Bennett in the United States proved that far larger rewards might come from the sale of fresh and comprehensive intelligence than from that of party opinion.

The third stage in the development of the profession, that of individualistic leadership, witnessed the rise of a series of great editorial moulders of opinion. In the United States there were Greeley, Bryant, Dana and Godkin; in England Edward Sterling, John T. Delane and F. H. Hill; in France Lamennais and Prévost-Paradol. The profession now at its best level not only was dignified and lucrative but offered some great prizes in fame and influence. The leading Anglo-American editors exercised a power not inferior to that of the principal statesmen, and independence was an indispensable part of this power. On the continent and especially in France the professional journalist had close relations with the professional literary man, and in figures like Sainte-Beuve, whose essays appeared in the *Constitutionnel*, the *Temps* and the *Moniteur*, the two often became one. The fourth phase in the evolution of journalism witnessed a singular obliteration, at least in English speaking countries, of this individualistic leadership. Journalism was more and more affected by the vast proliferation of newspapers and other periodicals, the rise of news associations and syndicates, the increase in the semi-educated public, the ever growing demand for news over opinion and the heavier financial dependence on advertising. It became more of an impersonal mechanism—more complicated, more departmentalized and more standardized.

The professional character of the journalist has thus closely reflected social and economic changes from generation to generation. In the United States, for example, we find first a printer running a job-office and stationery shop in connection with a dingy weekly; then a party pamphleteer publishing long essays signed Brutus or Camillus; then an alert purveyor of news like the elder Bennett or a master of editorial thrust like Samuel Bowles; then a specialist sinking his personality in some department of a huge machine—answering to the eras of colonial provincialism, of eager political speculation, of pioneering individualism and economic laissez faire, and finally to the complex society of modern times. In Europe the evolution of the profession has similarly corresponded to that of society itself.

The journalist's early conception of his work in all countries lacked dignity. Dr. Johnson and others speak of the Grub Street hacks and political hirelings who infested the profession in England, and much French journalism during and after the Revolution was disgraceful. Bal-

zac's picture of the calling in *Les illusions perdues* is scathing. In the United States Bryant in the 1830's decried journalism as wrangling, brutal and vulgar; it attracted many ill trained men and Greeley thought a college education a positive disqualification; its ethical standards were weak and until long after the Civil War few American journals were closed to the more insidious forms of bribery; its relations to other callings were vague and it was widely regarded as a feeder to letters, law, politics or business. As reflected in literature, from Dickens' Jefferson Brick of the New York "Rowdy Journal" in *Martin Chuzzlewit* to Howells' Bartley Hubbard in *A Modern Instance*, the working journalist was likely to be a sorry figure. Some traditions of the printer-journalist era still survive and to many practitioners in all countries journalism is still a craft or "game." But as the profession has developed it has gained steadily in dignity. Lincoln greeted W. H. Russell of the London *Times* as he would have greeted a foreign minister, and in fact told him that the *Times* was the greatest power he knew except perhaps the Mississippi River.

The greatest recent change in the profession has been the specialization entailed by the complex task of gathering news from a thousand sources to satisfy a multitude of different demands. This specialization has gone furthest in English speaking countries, where newspapers are most bulky and comprehensive, but it is felt everywhere. Until the latter part of the nineteenth century the typical newspaperman was necessarily a jack-of-all-trades, as on small newspapers he must still be. But the large city daily of today from Buenos Aires to London includes two separate categories of specialized workers. Under the business manager (to use American nomenclature) are the advertising manager, circulation manager, promotion manager, mechanical superintendent and auditor, each with a force of skilled workers. The editorial department includes the editor and editorial writers—managing editor, city editor, telegraph editor, financial editor, dramatic and literary editors, sports editor and perhaps also the political editor, women's editor and real estate editor, with reporters and correspondents. News gathering now requires reporters skilled in some branch of human activity, such as politics, aviation or finance; expert rewrite men to handle not only copy from correspondents, press associations and other sources, but information telephoned from street reporters; and experi-

enced copyreaders. In metropolitan dailies headline writing, make up and feature writing are each assigned to specialists. Journalism in its larger definition now includes trade papers, magazines, sports papers, press associations, free lance writing and publicity work, and each of these also demands some special equipment. Thus training for the profession increasingly requires not only a general education and some talent or flair, but technical knowledge of a particular kind. Nearly all newspapermen have mastered a set of fundamental tools; the best must learn to master some unique tool as well.

As in law and medicine specialization has meant a steady increase in the tuition period, the establishment of schools and college courses to prepare men for the profession, a sharper distinction between the expert and the amateur and more insistence within the calling upon standards of ethics, dignity and accuracy. Journalists in all countries are still largely recruited from high schools, trade schools and general college courses, but they must go through a protracted apprenticeship. In some countries this apprenticeship has taken on a fairly formal character. In Austria, for example, the beginner enters as an "editorial stenographer" (roughly what the Anglo-American press calls a copyreader) and mounts the rungs.

Since 1900 there has been an almost world wide debate upon the value of schools of journalism, many defending such schools as making for a more expert profession and others declaring that practise is the best training and that schools will force a host of untalented and ill adapted men into the calling and lower the conditions of employment. It is in the United States that schools of journalism have been most highly developed. The first was founded in 1908 at the University of Missouri; others rapidly followed in other state universities; in 1912 the Pulitzer School was established at Columbia University; and in the same year the American Association of Teachers of Journalism was organized. By 1930 more than fifty American colleges and universities were offering full curricula in journalism, and hundreds of single courses were being given in other colleges and in high schools. The average annual number of graduates of schools of journalism in the years preceding 1932 approached 1000. Initial distrust has been largely overcome and until the depression which began in 1929 employment was easily found. The special training had largely justified itself.

In other countries the development was later but almost equally rapid. In Germany during the ten years after the World War schools of journalism were established in sixteen universities, two technical schools and five higher commercial schools; some, like the institute of journalism at Heidelberg, are notable for thoroughness. The University of London in 1919 opened a cycle of courses in journalism leading to a diploma in two years. The British National Union of Journalists at first distrustful of such schools has recently attempted to promote courses in journalism in various centers and has arranged university courses for the supplementary education of newspapermen already practising their profession. Australian universities have developed courses in journalism and the University of Queensland offers a special degree; several Canadian universities have schools like those of the United States; and there is a school of journalism at the University of Madras. In Italy one of the five sections of the Fascist Faculty of Political Sciences created at Perugia in 1928 is devoted to politics and journalism. The International Labour Office in 1928 found that special education, while still experimental, is making progress the world over.

Professional organization like professional training is as yet new and uneven. In numerous countries it received a strong impulse from the economic difficulties which journalists experienced after the World War. But there are parts of Europe in which journalism is as yet scarcely a full time profession; in Spain, for example, it is carried on largely by men in other callings who make it a spare time employment. Organization is impeded in other countries and especially in the United States by the fluidity of the profession, which finds recruits everywhere and whose members are highly migratory. The strongest professional organization numerically is the National Union of Journalists in Great Britain which was founded in 1907 and twenty years later numbered nearly half of the 10,000 working journalists of the country. It has followed a resolute trade union policy and is affiliated with the Printing and Kindred Trades Federation. Australia also has a strong Journalists' Association with a trade union character. In Germany the Reichsverband der Deutschen Presse divided into twenty regional unions had a membership of about 4400 in 1928 and has been able to do much in safeguarding the social and economic interests of the members. Organization in Italy has a considerable history,

culminating in the establishment in 1925 of the *Sindacato Nazionale Fascista dei Giornalisti*, partly political and partly trade union in character. The only comprehensive French organization is the *Syndicat des Journalistes*, numbering about 1200 members in 1927, which has a defensive economic aim. Various efforts have been made in American cities and in Canada to form professional bodies of a trade union character, but they have uniformly broken down. In Europe and Australia not a little has been accomplished in negotiating collective agreements on hours, salaries, holidays and the settlement of disputes; uniform contracts have sometimes been drawn up, and in Austria, Hungary, Italy and a few minor countries protective legislation has been obtained.

The opportunities and rewards of the newspaper profession, although uncertain and irregular, have manifestly risen in recent years. The great body of working journalists probably receive a little less than the general body of doctors and lawyers and a little more than the general body of teachers. In France in 1926 the *Syndicat des Journalistes* obtained a Paris agreement that journalists of two years' experience should receive not less than 1200 francs monthly. In Berlin a journalist may not be paid less than 440 marks a month. The highest pay is found in English speaking countries. In Great Britain in 1921 the National Union of Journalists negotiated a minimum weekly salary of £5/15 for its members working in cities of more than 250,000 people and £5/3 for members on dailies in towns of less than 100,000. Some London journalists have munificent incomes. In New South Wales and Victoria an agreement of 1924 fixed salaries for three categories of journalists, ranging from £5/19 weekly for juniors on evening metropolitan dailies to £10/12/6 for seniors on morning dailies. American reporters are in general given small salaries, but the best rewards run very high. In New York City in 1929 salaries to department heads and special writers reached \$500 a week, and in a typical city of 500,000 they were \$225 a week; noted syndicate writers make from \$40,000 to \$100,000 a year; one or two column writers make even more; "accounts executives" in advertising departments on metropolitan dailies make \$25,000 to \$75,000 a year; exceptional men in the fields of publicity and "comic strip" illustration may have an annual income between \$100,000 and \$150,000. The chance of obtaining an exceptional income and the fear that a minimum wage

would also become a standard wage have been among the chief forces militating against a trade union movement in America.

Journalism is notoriously a harassing and exhausting profession. Hours are long and on morning journals often extend to 2 or 3 a.m. The frequent changes in proprietorship, the numerous consolidations of newspapers in the United States, Great Britain and the dominions, the revolutionary upheavals in ideas on the continent have all made employment precarious; and the working life is short, many men being worn out at fifty. Press associations in France, Germany, Austria and Great Britain have made active efforts to deal with unemployment, but no such assistance is given in the United States. Provident institutions of a professional character are numerous in Europe; Great Britain, Germany, Italy, France and other countries possess mutual aid funds which furnish old age pensions and often unemployment and sickness benefits. They are unknown in Australia and the United States, although a number of large American papers have instituted insurance funds for their own employees and there are two American homes for aged journalists, one founded by the second James Gordon Bennett. Better provision for professional casualties is in general a crying need in the newspaper world.

For the dignity and repute of the profession nothing is more important than the organized promotion of good ethics and accuracy. There is in all countries a large field for improvement in this respect. The venality of much of the French press has been exposed in repeated scandals. It is matched in other Latin countries of Europe and South America. In the United States vulgarity, slovenliness and sensationalism are far greater evils. The most honest, sober and intellectually respectable journalism is that of Great Britain, where a long line of journalistic leaders have established traditions of continuing power. Professional standards there are watched over by the Institute of Journalists, founded in 1880 by royal charter and including newspaper proprietors as well as workers. The National Union of Journalists with its monthly organ the *Journalist* also gives effective attention to the subject. The United States has no similar body, although there is manifest room for a journalistic counterpart of the American Bar Association or Medical Association. State and national associations of newspaper publishers, maintained for many years, have confined themselves mainly to business ob-

jects. The American Society of Newspaper Editors founded in 1922 had a membership two years later of 174 editors in cities of 50,000 or more, but it lacks scope and authority. At its second meeting in 1923 a code of ethics dealing with independence, truthfulness, accuracy, impartiality and decency was adopted, and although it had more resonance than practical value it marked a beginning. In 1912 the first National Newspaper Conference, addressed by many leaders, was held at the University of Wisconsin. In 1914 the second conference met at the University of Kansas and others met subsequently. State press associations have adopted codes of ethics. One valuable force for honesty in American business offices is the Audit Bureau of Circulations which carefully audits publishers' statements of circulation and issues standardized and accurate statistics for the benefit of advertisers. Bills introduced in state legislatures to license journalists in the same fashion as doctors and lawyers have invariably failed. Several newspapers, notably the New York *World* in its last years, have set up bureaus of accuracy and fair play. The old evils of bribe taking and blackmailing have largely disappeared in the United States. But newspapers are frequently unjust to individuals and news of libel suits is tacitly but systematically suppressed in most newspaper offices. Many journals color or suppress news to suit their advertisers; there is much mendacity, distortion and sensationalism in weaker parts of the press and particularly among the "tabloids" or small size dailies; and a subcommission of the New York State Crime Commission declared in 1927 that many newspapers made heroes of criminals, tried cases in their columns and influenced adolescents to emulate crooks and gangsters.

As a profession journalism the world over suffers from the brevity of its history and a consequent lack of firm traditions; from the process continued generation after generation of annexing new bodies of readers by establishing journals which reach out to the ignorant, illiterate and vulgar minded; from the frequent difficulty of reconciling the objects of the editorial departments with those of the counting room; and from the great recent tendency in many countries toward consolidating rival newspapers, suppressing individuality of tone and making the surviving journals commercial in character. A constant struggle is required to maintain or elevate journalistic standards. In Great Britain and the United States, the two countries where

journalism has counted for most, persistent complaints of deterioration have been heard in recent years. Yet materially the newspaper has had and is still having a prodigious development. Great strides have been made since 1900 in developing a specialized education, in bringing into existence professional organizations of a trade union character and in improving both the economic status and the general repute of the profession. It has more esprit de corps than before, manifest in local, national and even world associations; it presents a steadily widening range of openings for individual talent; in some directions it is more progressive than heretofore. It furnishes less of strong personal leadership and striking individual talent than it did in the nineteenth century, but as a routine occupation for a great mass of workers it is slowly rising to better levels and offering increased attractions.

JOURNEYMEN'S SOCIETIES were created in the period of the decay of the mediaeval craft guild by artisans (*valets*, *varlets* or *compagnons* in France; *Gesellen* in Germany; journeymen or yeomen in England) who had completed their apprenticeship but had not attained mastership. In theory at least the mediaeval guild had united journeymen and masters, treating them not as fixed classes but as two different stages in the development of any competent artisan. But with the first appearance of capitalism and the drive toward the attainment of a monopoly of the sources of private gain the masters deprived the journeymen of representation in the guild assemblies. In the cloth industry, which because of its technique and commercial position was the first to assume a capitalistic character, the differentiation into classes began not later than the

fourteenth century. By the sixteenth century a permanent class of journeymen had been created throughout western Europe. Various devices were contrived by the masters and through them by the government to place the mastership virtually beyond the reach of journeymen. The period of apprenticeship was extended; according to the provisions of the English Statute of Artificers (5 Eliz., c. 4), for instance, it was fixed at seven years. Dues and entrance fees were increased and more costly gifts and banquets demanded of candidates for the mastership. The masterpiece, which the prospective master was obliged to furnish everywhere on the continent as well as in several crafts in England, became a virtually prohibitive requirement, as it was made progressively more costly and difficult to achieve. The journeyman might with difficulty rise to the intermediate rank of small master. But the latter class was subjected to the same treatment, until by the seventeenth century it consisted almost entirely of wage earners. The masters of the *corps de métier* in France and of the livery companies in England came to form closed oligarchies tending to bequeath their jealously guarded monopolies from father to son. Sometimes as a direct result of their elimination from all influence in the guild, sometimes, as in Paris in 1530, by special decree, the journeymen—now unhonored *gens mécaniques*—were ousted from the government of the city. The maltreatment of them occasionally took a violent form, as at Chester in 1358; and there is evidence that they were persecuted by law throughout Germany and at Paris, Châlons, Rouen, Amiens and Troyes in France.

In self-defense the journeymen began to form independent associations with their own chiefs and treasuries. The early *compagnonnages* in France, particularly those in the southwest, had a religious, charitable character, like the *Bruderschaften*, which were the first *Gesellenverbände* in Germany. In the fifteenth century fraternities of journeymen or yeoman cordwainers, saddlers, tailors and other craftsmen were founded in London and later in other English cities. Through these organizations the journeymen were able to defend their position in the companies, an aim which they pursued first in cooperation with the small masters and then independently. From 1434 the Blacksmith Company in London was forced to accept the presence in its midst of a special organization of journeymen.

The journeymen's societies soon undertook the surveillance of handicraft. Such superin-

tendence had been initiated in Paris in 1406, when the masters filed a complaint that every journeyman arriving in the city had to regale the other workers in a roisterous holiday at his expense. Especially in Germany and France the working population was largely mobile. The idea that the workman must travel in order to perfect his moral education and his professional training was deeply embedded; if he were a mason, for instance, he had to see the famous monuments. The obligation to travel, the *Wanderschaft*, seems to have been first introduced in Germany, probably in the fourteenth century; in that country the period sometimes lasted as long as five years. The *tour de France*, as the same requirement was called in France, was still practised in the middle of the nineteenth century, as evinced by Agricola Perdiguer's *Le livre du compagnonnage* (1839) and George Sand's *Le compagnon du tour de France* (1840). In each town that he visited the young journeyman had to register at the *Herberge* of his craft—in France the innkeeper's wife was called the mother of the journeymen—and then to present the password to the secretary of the society, who provided him with work or, if none was available, with funds to continue his travels (*viaticum*).

Out of these practises there evolved a complex and, to outsiders, mysterious ritual. Assumed names, cryptic gestures and words, the wearing of colored ribbons and the carrying of canes provided means of identification. Elaborate festivals were held; a system of dues, fees and fines was established; "secret" correspondence was conducted between the various local branches of the craft. The ceremony of initiating new members under pledge of secrecy represented a naïve imitation of the church cult. Through these rites a connection has been traced between the journeymen's society and the origins of Freemasonry. The name is thought to have derived from a fraternity of *freie Maurer*; according to one theory the *freie Maurer* founded in the thirteenth century at the Cathedral of Strasbourg constituted the first *Bauhütte*, or lodge, of the order. The myths of the French societies are strongly suggestive of a link with Freemasonry. Divided into three large groups or *devoirs* on the basis of their legends and professed genealogy, the *compagnonnages* claimed descent from the Order of Templars or even more remotely from the architects of the Temple of Solomon. The most likely hypothesis is that the intellectual societies created in England and

Scotland in all probability at the end of the seventeenth century took over the rites and symbols of the journeymen builders together with the name of Freemasons.

Because of the secrecy involved the symbolism of the societies inevitably aroused suspicion and led to charges of sacrilege. In 1655 after information had been furnished by spies of the *Confrérie du Saint-Sacrement*, a society of the devout which served the interests of the employers, the Sorbonne condemned the French *compagnonnages* as impious. The political authorities pursued them also as disturbers of the peace—an accusation not without some foundation since the members of the rival *devoirs* were constantly squabbling and sometimes engaged in sanguinary battles.

The picturesqueness of the journeymen's societies has tended to divert attention from their essential purpose. Primarily they were organs of workers' defense against nascent capitalism. Through their hold over the traveling worker upon his arrival in town the societies could attempt to monopolize the placement of workers and to exercise an indirect control of the labor market. When their demands were refused, they withheld a supply of workers from the masters and sometimes even from an entire city. Similarly, those workmen were banned who disobeyed the orders of the group, failed to pay their assessments or agreed to work at bargain rates. The societies, in short, conducted an organized persecution of scabs. The masters found themselves at odds with the societies if they exceeded the number of apprentices authorized by the rules of the trade, thus diminishing the number of paid workmen, or if they reduced wages, nominal or in "bread, meat and drink." The complaint of the printers of Lyons in 1539 included both charges; the cloth workers of London petitioned against the first action in 1568, 1574 and 1577, on the last occasion eliciting the reply from the Court of Assistants—the title of the oligarchical councils of the English guilds—that "they must come to their work at such time as they ought to do by the ordynance of this house, and to do their work justly and truly as they ought to do, and to be content with such reasonable fare." A third object of protest on the part of the societies was the excessive length of the working day.

These conflicts frequently ended in strikes, called variously monopoly, *tacquehan*, *tric*, *cabale*. During the thirteenth century the cloth workers struck at Rouen, Provins and Beauvais.

The great printers' strike which broke out at Lyons in 1539, ten years after the general rebellion of the *secte artisanne* of the same city, spread to Paris in 1541 and was finally settled only in 1571. These strikers had a strike fund and an almost military type of organization and the strike was punctuated with outbursts of violence. It was against such activities as well as for religious reasons that the *Confrérie du Saint-Sacrement* organized devout, docile workmen into *bons compagnonnages*, which became genuine strike breaking societies. In general government was at all times and in all places hostile to journeymen combinations. The Imperial Decree of 1731 provoked by the strike of the Augsburg shoemakers was one of innumerable attempts at suppression made by the German authorities. In England immediately after Elizabeth's comprehensive statute on industrial regulation journeymen were condemned for having "unlawfully consulted and assembled together from their master's service." In France journeymen combinations were prohibited in 1539 by the royal decree of Villers-Cotterets, which was many times reissued under the *ancien régime*. During the revolution the Law of Chapelier of 1791, making it a crime for citizens of the same profession and for any workmen to organize or to attempt to regulate their alleged interests, was dictated by fear of journeymen's strikes, particularly in the food industry and builders' and carpenters' trades. All the laws in France against combination down to 1864 and against association down to 1884 may be connected with a similar fear.

Explicable partly by the emergence of large scale industry, partly by the universalization of the *Wanderpflicht*, a general federative movement linking up local societies into powerful organizations set in sometime before 1700 and lasted until the end of the eighteenth century. This provides at least one explanation for the survival of the societies in the face of the unintermittent hostility which they aroused. In Germany, where the *Wanderpflicht* had become established earliest, great federations spreading a network sometimes over the entire nation had been created in the sixteenth and seventeenth centuries. Letters patent of 1777 state that throughout France the paper makers, who were particularly susceptible to the movement because of the scattered distribution of the paper mills along the waterways, "have united in a general association by means of which they control the industry as they please." In eighteenth century

England on the eve of the modern trade union movement the journeymen hat makers had a widely ramified organization. The London Felt-makers' Company consisting of the master employers registered a denunciation in 1777 of a journeymen hat makers' combination, "called a Congress," which made by-laws for the whole trade and had a system of fines and sanctions. The comparatively veiled activities of the hatters during the century eventuated in 1798 in the formation of the Journeymen Hatters' Trade Union of Great Britain and Ireland, which is still in existence. Sometimes the federation exceeded state limits; for instance, the hat makers of Brussels were in correspondence with their fellow craftsmen in French towns.

After temporarily subsiding during the revolution the French journeymen's societies revived and gave the imperial administration as well as the Restoration government more than one occasion for concern. But the progressive development of the factory system and of machine technique, the emergence of specialization, standardization rendering the *Wanderschaft* superfluous, as well as internal weaknesses arising from exclusivism and feuds with rival societies, made journeymen's societies increasingly insignificant. Since the advent of the trade unions they have lost all influence in France as in England, although traces of them are to be found even today. Associations formed among the workers of various trades in America toward the end of the eighteenth century took the name of journeymen's societies. The primary object of most of these early American societies was mutual aid and benefit, but during the first half of the nineteenth century many American journeymen's societies organized strikes. In Germany *Gesellenvereine* still exist, for instance, among the bakers, while the journeymen's committees, *Innungen* and craft guilds recognized by the *Gewerbeordnung* of 1929 represent vestiges of the old institution. The Catholic *Gesellenvereine*, founded at Elberfeld in 1845 and at Cologne in 1853 by Adolf Kolping, "father of the journeymen," reckon more than 300,000 members and are in correspondence with a Kolping Society of America.

Admitting only able and conscientious artisans, the journeymen's societies set for their members a high standard of workmanship as well as of moral conduct. They improved and diffused the techniques of industry. In general they were animated by a lively fraternal spirit which found expression not only in festivals but

in a generous expenditure from their treasuries for purposes of mutual aid and in the establishment of funds for non-interest bearing loans. They rather than the craft guilds are to be regarded as the real forerunners of the trade unions. While their protests against the employers were comparatively sporadic, they occupied a position in the defense of labor for which no other organization before the trade unions competed.

JOVELLANOS, GASPAR MELCHOR DE (1744-1811), Spanish statesman, economist and educator. Jovellanos studied philosophy, theology and law at the universities of Oviedo, Ávila and Alcalá. In 1767 he was appointed magistrate in Seville and eleven years later was transferred to Madrid. He served as minister of justice under Charles IV in the year 1797-98. Because of his political affiliations he was twice exiled. He refused the Ministry of the Interior which was offered him after the French invasion by Joseph Bonaparte and became a member of the Junta Central for Asturias, collaborating actively in the work preparatory to the Cortes of Cadiz. In his *Memoria en que se rebaten las calumnias . . . contra los individuos de la junta central* (2 vols., La Coruña 1811) he propounds his conception of

the ideal state: a limited constitutional monarchy in which the executive, legislative and judicial powers are clearly separated.

Jovellanos is identified in general with the group of enlightened Spanish statesmen of the eighteenth century who sought to improve the economic position of Spain. He was distinguished for his encyclopaedic learning and wrote poetry and drama as well as innumerable treatises on economic and political questions. Although he accepted in general the theses of the liberal school of economists he frequently offered opinions in contradiction to their teachings. His chief work in this field is his famous *Informe . . . en el expediente de la ley agraria* (Madrid 1795, new ed. Gijón 1891), a report made to the Supreme Council of Castille for the Sociedad Económica of Madrid. The document, still a classic in Spain, contains a clear and methodical exposition of the obstacles to Spanish agricultural progress, obstacles including not only the nature of the soil and adverse climatic conditions but also existing law and custom. To remedy the situation he advocated irrigation and improved roads, the break up, for sale or lease, of the commons and waste lands, the abrogation of the privileges of the Mesta and the education of the peasants. He favored free trade in grain within the country but objected to its export and believed that its importation should be limited. In *Informe que dió á la junta de comercio y moneda sobre el libre ejercicio de las artes* (Madrid 1785) Jovellanos urged the abolition of the craft guilds, maintaining, however, that some regulation of the crafts was necessary.

Conscious of the needs of practical and technical education, he founded the still existing Real Instituto Astoriano in Gijón and organized the curriculum, which in addition to mineralogy, mathematics, physics and the nautical sciences included courses in modern languages, history and geography. Jovellanos himself wrote a number of the textbooks, covering a variety of subjects. His *Reglamento* (Salamanca 1790) for the Imperial College of Calatrava outlined the most complete plan of studies to be found at that time in Europe. Jovellanos held that with the extension of the suffrage popular education became a social necessity and that the government must provide it.

JOWETT, BENJAMIN (1817-93), English scholar and educational leader. Jowett was tutor of Balliol College, Oxford, for twenty-eight years and master for another twenty-three. His fundamental educational principles were sympathetic intimacy between tutor and pupil, strict but unmechanical discipline, examinations which would be selective of ability and acceptance of the obligations of corporate life. He urged the opening of all doors to poor students of intellectual promise and worked for the extension of secondary and adult education. His devotion to Balliol was unsparing and his labors for its improvement endless; he enlarged buildings, spending much of his own money on the college; encouraged athletics; fostered the teaching of physical science; inaugurated intercollegiate lectures; reduced expenses for poorer men. During four years as vice chancellor of the university (1882-86) he safeguarded the beauties of the parks, drained the floods, accelerated the production of the *Oxford New English Dictionary*, encouraged oriental studies and the drama.

Jowett believed strongly in the vitality of classical culture; and his translations of Plato (1871), Thucydides (1881) and the *Politics* of Aristotle (1885) are classics in themselves. His theological writings, however, exposed him to suspicion of heresy. Although he remained unshaken in the innermost chamber of personal faith he was a rationalist in criticism of formulated dogmas. He held that the perfect liturgy will contain no creeds and that the spirit of Christianity is not always identical with the letter of the Bible. Such views, which were first apparent in his edition of the epistles of St. Paul (. . . *Epistles to the Thessalonians, Galatians, Romans*, 2 vols., London 1855; 2nd ed. 1859), were very distasteful to orthodox opinion, but established a place for him among the leaders in modern Biblical interpretation.

JUÁREZ, BENITO PABLO (1806-72), Mexican statesman. Juárez, a pure blooded Indian of peasant stock, was educated in the law. In 1855 an uprising of mestizo and provincial interests against the church and the great landowners expelled the dictator Santa Anna and initiated a great Mexican reform movement, which Juárez supported; he became minister of justice and chief justice and when intrigues brought about the downfall of the reform government proclaimed himself acting president. He achieved victory in the bloody War of the Reform from 1858 to 1861 and expelled the papal nuncio and other ecclesiastics who resisted his decrees. The clericals and monarchists sought foreign support for their cause, but Juárez met the joint military intervention of Great Britain, France and Spain in 1861-62—ostensibly for the purpose of collecting debts and reparations for damages suffered by their nationals in the civil conflicts—with dignified and prudent negotiations. When the French remained behind to wage a war of conquest in the clerical interest and to establish a Hapsburg empire under Maximilian, he displayed a courageous and untiring resistance, which contributed toward a great development of the national consciousness. The initial measure of the reform was the so-called Juárez Law of 1855, which practically suppressed the military and ecclesiastical tribunals as class courts. More anticlerical legislation followed and a national convention established the liberal, federal constitution of 1857, the basic document, in spite of all vicissitudes, of Mexican political life down to 1917. During the civil war Juárez promulgated a comprehensive group of reform laws, which in part confirmed previous legislation and which together with other measures confiscated the immense landed holdings of the church, dissolved the monasteries and convents, proclaimed the separation of church and state, secularized the cemeteries and made marriage a civil contract. His government also enacted measures contemplating the creation of a class of small landowners. Upon the downfall of the empire Juárez reestablished the federal and republican regime; he was elected constitutional president in 1867 and reelected in 1871. Al-

though his administration showed less concern with implanting a genuinely popular and constitutional government than with its continuance in power, he negotiated advantageous treaties, strove to keep the military in their place and gradually restored a considerable degree of civil order. Today he is revered by most Mexicans as their greatest national hero and the champion of their popular rights. Some, however, have condemned the rather onerous conditions which he accepted in 1859 as the price of recognition by the United States and many have questioned the wisdom of the occasionally radical application of the principles of liberalism and individualism, as developed in Europe and the United States, to Mexico, with its large aboriginal population and its religious and collective traditions.

JUBAINVILLE, HENRI D'ARBOIS DE (1827-1910), French historian, philologist and jurist. D'Arbois de Jubainville was the founder of Celtic studies in France. Archivist at Troyes from 1852 to 1880, he published numerous works on the archives and the archaeology of the Aube and a seven-volume history on the counts of Champagne from the fifth to the fourteenth century. In order that he might understand the origins of France he learned the Celtic languages and became a philologist and historian of antiquity. In this new domain he attracted universal attention with a great work, *Les premiers habitants de l'Europe* (Paris 1877; 2nd enlarged ed., 2 vols., 1889-94). The chair of Celtic was created for him at the Collège de France in 1882, and he became a member of the French Institute in 1884. He was the author of many articles on Celtic philology and published a *Cours de littérature celtique* (12 vols., Paris 1883-1902), of

which seven volumes were composed by him, the others by his pupils.

Since his youth d'Arbois de Jubainville had been interested in the history of law. He had indeed begun by studying law at the École des Chartes. He now returned to the law by way of philology and published a famous work, *Recherches sur l'origine de la propriété foncière et des noms de lieux habités en France* (Paris 1890). Thereafter he occupied himself almost exclusively with Celtic law, which he alone was equipped to study at its sources since he was both Celtist and jurist. He devoted particular attention to Irish law, especially the *Senchus Mór*. His "Études sur le droit celtique" (vols. vii-viii of *Cours de littérature celtique*) and his *La famille celtique* (Paris 1905) are among his most important works in Celtic law. As historian he dissipated many of the fantasies concerning the ancient Gauls, and as jurist he put the study of Celtic law upon a scientific basis.

JUDAISM. Nineteenth century historians of religion, especially Christian historians, have used the term Judaism to denote the religion of the Jews since the time of Ezra (c. 444 B.C.) in contrast to the pre-exilic religion, which they called the religion of Israel. This attitude was prompted primarily by the belief that postexilic Judaism was a retrogression, due to foreign influences, from the teachings of the prophets and that the true prophetic tradition was continued in the religion of Christianity. Closer study of the sources has revealed more and more clearly, however, that Judaism is but a continued development of the teachings of the prophets. Like every other religion Judaism passed through a certain historical evolution, throwing off old elements and acquiring new ones. Foreign influences were always operating—from the earliest influences of Egypt, Babylonia, Assyria and Persia through the Hellenistic period, the contacts with Arab culture in the Middle Ages, the humanistic tradition of the Renaissance down to the influence of Protestantism on the development of reform Judaism. One or another aspect or tendency may have been especially stressed or become dominant, but until the close of the

eighteenth century there was never a radical break with the main tradition and characteristic form which Judaism assumed during the period from Ezra to Akiba (c. 135 A.D.). Rather it was constantly reinterpreted in the course of centuries and adhered to with astonishing fidelity.

The most primitive form of the religion of Israel was developed probably during the nomad period. It was characterized by a belief in demonic powers and spirits, by distinctions between clean and unclean animals and by adherence to certain death customs. It already contained, however, the germs of the ethical ideas later developed by Moses and the prophets, and monolatry rather than polytheism prevailed. With the entry of the Hebrews into Canaan and their development as an agricultural people came also a development of a cultus marked by sacrifices, festivals and sanctuaries. This period is also marked by a struggle between the religion of Yahweh and the continued attempts at incorporating the worship of local deities.

It was in connection with this struggle that there appeared in Israel a group of men unique in the history of the ancient world who brought the development of the Hebrew religion to its highest point. The prophets were men of diverse social classes whose authority was based on the fact that they were responsible to their God alone and who were independent and courageous enough to proclaim what had been revealed to them, even though their prophecies announced serious disasters involving the ruin of the whole nation or the destruction of the temple. Their teaching was marked by a pure ethical monotheism and universalism, a passion for social justice and a repudiation of the sacrificial cult as the most distinctive mark of the Hebrew religion. But the prophets were never able to establish the complete supremacy of their ideas and the cruder forms of popular belief persisted side by side with these more spiritualized religious and ethical precepts.

After the Babylonian exile the leadership of the people became hereditary in the priestly house of Zadok. By this time too the Law had been reduced to writing and through the efforts of Ezra and the traditional Men of the Great Synagogue had been restored as the most essential factor in the Hebrew religion. This Mosaic law circumscribed the activities of the priestly class and became the most effective means of making the teachings of the prophets the inheritance of the individual. The task of furthering this usage of the Torah (Law) was assumed by

a new order of scribes, who came from the people and who by their personal qualifications proved their fitness for this high calling. The prestige of the scribes grew especially during the period when the hereditary priesthood temporized with the inroads of Hellenism. The scribes assumed the leadership of the middle class and peasantry in a successful fight for the preservation of their national and religious integrity. When a new priestly class developed which gathered about it the Sadducee aristocracy and founded a new dynasty, they were challenged by the pietists of the middle class, now known as Pharisees, who continued the tradition of the scribes. The Pharisees set up an ideal based on the democratic belief in universal priesthood and on the conviction that man's entire life and activity should be permeated by a sense of piety. It was at this time too that the concept of an oral tradition in addition to the written law came to the fore. The Pharisees, in opposition to the Sadducees, affirmed the divine and binding character of the oral law as developed by the scribes and the rabbis. Although this doctrine was at first vehemently contested by the various sects yet it was this doctrine more than anything else that preserved the vitality of the Torah and made possible the development of Jewish life. The Pharisaic conception was the only one that was able to maintain itself after the fall of the Jewish state and the destruction of the temple. The teachers of the Torah became henceforth the unchallenged leaders of the people.

The Pharisees, later known as *tanaim* and then as *amoraim*, were likewise men of diverse social classes; they were kept together and enabled to exert their influence over the people by their common work and ideal. It was they who transmitted and developed the oral tradition and it was their doctrine and their opinions that became decisive for the Jews of the whole world. Their decisions determined the laws, customs and religious ceremonies of Jewry. These, however, were never promulgated in either dogmatic or mandatory form; they were accompanied by statements of the controversies and discussions which their formulation had required, in order that later generations might be able adequately to understand the mind and will of their predecessors.

The opinions and decisions of the *tanaim* and *amoraim* are contained in what has come to be known as the Talmud, a vast encyclopaedic storehouse of legal opinions, controversies and

decisions; of ethical precepts and maxims; and of legends, history and traditions, which received its definite written form about the year 500. Only a secondary place was given in the Talmud to the treatment of religious creed, for in this sphere considerable latitude was allowed. Chief attention was directed to the practises which were to regulate the legal and ritual life of the Jews. With the exception of the Karaites, who, beginning in the eighth century, formed a separate sect and refused to recognize the validity of the oral tradition, all the Jews willingly submitted to the authority of the Talmud. The initial success of Karaism (today it has about 12,000 adherents) was of short duration. The whole movement soon became culturally petrified. The principles of rabbinical Judaism, on the other hand, made possible a continuous cultural development. The Talmud met with recognition but never with blind worship; no matter how strong the bonds of tradition, alert and eager commentators and codifiers always started afresh and by their work tried to do justice to the changes in social and cultural conditions. Because there were no rigid and absolutely binding rules of interpretation and no central or final authority, each commentator decided on the basis of his personal convictions how much weight to give to the work of his predecessors. In most cases, however, the commentators endeavored to find substantiation for their views in the Bible and the Talmud or in the work of a previous rabbi; it was seldom that they dared to contradict an uncontested opinion in the older literature. Codification of the vast material soon proved to be necessary, but even the *Mishna torah* of Moses Maimonides (1135–1204), which is distinguished for its completeness and logical unity, did not meet with general approval. The *Shulchan aruch* of Joseph Karo (1488–1575) also aroused great opposition at first, but it was gradually accepted after the glosses of Moses Isserles (died 1572) had been incorporated into it and after it had been further modified and reinterpreted by numerous commentators. In orthodox circles the *Shulchan aruch* thus amended still enjoys decisive authority. The critical attitude toward it which Chassidism originally assumed was soon abandoned and its authority was submissively acknowledged.

Traditional Judaism as developed in the Talmud, the rabbinical literature and codes of the succeeding ages came to regulate the entire life of the Jew. Judaism made no distinct cleavage

between the sacred and secular aspects of life. Problems of morality, family life, hygiene, dietetics, business relations, sexual life, education and dress as well as of the more distinctly religious elements of ritual were encompassed within the range of rabbinic authority. All the legal minutiae were created by the rabbis as a "fence around the Law" to assure the preservation of the essential features of Judaism. Attacks have been made on this legalism of rabbinic Judaism, but it was this body of doctrine that supplied the independent Jewish communities scattered throughout the world with what Heine called a "portable fatherland," with a common possession which gave to the entire Jewry a common consciousness and a stamp of unity. This traditional literature of the Jews was the source both of the cultural life from which they derived their spiritual unity and of their continued cultural and spiritual progress. The system performed a further service for Judaism in identifying religion with the earthly life and in general removing the religious struggles within Judaism from the realm of dogma to that of the concrete, thus liberating human energy for human activity.

Side by side with the development of rabbinic Judaism there developed a doctrine of mysticism known as the Kabbala. Indications of these mystic strains in Judaism are already evident in the Talmud and in the Midrashic literature. The first important book of the Kabbala was the *Sefer yetzirah* (Book of creation), which became current about the ninth century. Kabbalistic literature continued to be developed among the Jews of France and Germany and in the sixteenth century flourished especially in Palestine, where it was cultivated by the schools of Moses Cordovero (1522-70) and Isaac Luria (1535-72). The *Zohar*, a work of unknown authorship, which became current in the fourteenth century, came to be considered as the most sacred of Kabbalistic writings. The Kabbala was developed along two lines. On the one hand it flourished as a metaphysical system concerned with the doctrine of divine emanation, with the concept of God as the Infinite (*En-Sof*), with the ten intermediaries, or *sefirot*, of God and with the doctrine of transmigration of souls (*gilgul*). Alongside of this speculative mysticism there developed a practical Kabbala which stressed the sinfulness of human nature, built up a system of demonology and magic, encouraged asceticism and was above all concerned with Messianism and the problem of the salvation of

Israel. It was this Messianic strain which inspired the later activities of Sabbatai Zevi and the Frankist sects. In a very much modified form the Kabbala was also one of the sources of the movement of Chassidism (*q.v.*). Related to the Kabbala was the didactic literature (*musar*) which grew up to satisfy the more emotional needs of the masses. The *Sefer chassidim* of Samuel Chassid (1115-80) and his son Judah Chassid (1150-1217) is the most typical example of this aspect of Judaism. It is a mixture of noble ethical principles with popular superstitions concerning evil spirits and demons. Generally speaking, both of these currents served as reactions to overdeveloped rationalism and as a correction for the overassertion of legalism. They had distinct social roots also, in that their appeal was greatest among the more humble classes.

The religious institutions of the Jews varied with the different periods of development. The centralization of the cultus at Jerusalem during the period of the first kingdom resulted in the displacement of the old local sanctuaries by the temple in Jerusalem. The temple became the central religious institution of Jewish life where all the important rites were to be performed. During the Babylonian exile the Jews preserved their religious traditions in assemblies where the scriptures were interpreted, the psalms or other religious poems recited, confessions made and prayers said either collectively or individually. This gave rise to a new religious practise, the prayer service, which from a casual and purely exilic device became a permanent practise recognized in Palestine and one of the most important innovations in the field of religion. There was brought into being a form of religious service which was independent of consecrated places, buildings, objects, classes and persons and which requires only the will of a group.

These assemblies knew no distinctions of rank; all their members no matter whether they were natives or strangers were treated as equals; even women were at first not excluded from the performance of certain functions. With these congregations the Jews created an extremely mobile type of institution. The synagogues, which were centers both of religious worship and of learning, accompanied the Jews in all their migrations, springing up spontaneously everywhere. It is from Judaism that its two offshoots, Christianity and Islam, borrowed this religious institution.

The prayer service acquired such an impor-

tance in Jewish life that it found its way also into the temple at Jerusalem; and when the temple was destroyed for the second time, the synagogue, this "sanctum in miniature," was sufficiently popular to offer in its devotional practices a substitute for sacrificial services. The victory of the secular synagogue was by this time complete, despite the few survivals of temple customs and the slight privileges which were granted "for the sake of peace" to the descendants of the old priests. The emergence of a class of professional readers was caused not by a desire to create a consecrated caste but by the technical needs of recitation. Even today all synagogal functions are open to every member of the community. The difference between laymen and ministers which characterized the synagogue in the last century marks a definitely backward step.

Evidence of proselytizing efforts on the part of Jews is found as early as the Exile period. During the Hellenistic period Jewish missionary activity was carried on through the Jewish literature in Greek, through the synagogue with its readings from the Bible and through personal influence, especially of the Jewish merchants. Conversion to Judaism was quite frequent during the early years of the common era. After the triumph of Christianity Jewish proselytizing was carried on chiefly in non-Christian countries, like Arabia and Abyssinia. The conversion of the Chazars is the most important instance of mass conversion to Judaism. A more subtle form of proselytizing is evidenced in the Judaizing sects of Protestantism and those of Russia. It was not until the time of Moses Mendelssohn that the doctrine was formulated whereby no one not born into the Jewish religion should be converted to it.

An attempt to construct a generalized statement of the leading social and ethical doctrines of Judaism is made difficult by the fact that the Bible and rabbinic literature abound in conflicting statements and opinions which can be used to support contradictory views on the same problems. The difficulty is intensified also by the absence of any central authority or court of last resort in the formulation and interpretation of religious problems. Certain leading principles have, however, been fairly constant; and in instances where earlier conflict existed one or the other opinion has come to be stressed and accepted under the influence of external conditions and the historical experiences of the Jewish people.

The basic idea of Judaism is its belief in revelation, that God revealed Himself to the people of Israel, that He disclosed to them His nature and will and that He made a covenant with them. The idea of God in Judaism is a direct continuation of the Mosaic concept of Yahweh as a single spiritual God of whom nothing but Being is predicated, and who is never worshiped in the form of images or statues. This doctrine precluded all polytheism, all worship of female deities with its consequent lasciviousness, all worship of animals and of the heavenly bodies. It forbade the worship of nature with its good and evil forces. It forbade child sacrifice, prohibited every form of magic and witchcraft and rejected ancestor worship and ancestor incantations.

The major prophets conceived of Yahweh as perfect and holy, as the principle of all spirituality; that is, as the one and only God. They dedicated all their efforts to supporting this conception and to eliminating all anthropomorphic elements from Judaism. There was thus established a solid foundation for the monistic conception of God and for the repudiation of all anthropomorphism which was able to withstand the force of foreign influences during the period of the Exile. No definite attitude was ever adopted concerning the question of angels and demons. The scribes paid little attention to them; following the old Biblical writers they regarded them simply as "messengers" and "instruments" of God. In the popular imagination, on the other hand, these beings grew in number and significance because of Babylonian and Persian influences. They were regarded by the people after the fashion of the retinues of earthly kings at court although still as subordinate creatures of God, whose unity was not thereby in the least impugned.

In Greek culture Judaism for the first time came into contact with a systematic and philosophic doctrine of God. The antithesis between immanence and transcendence, the dualism between God and the world, was most keenly perceived by the Greeks, who solved the difficulties involved by assuming the concept of a mediator. Greek culture gave rise to Philo's doctrine of the Logos—the Son of God—and also to the gnostic conception of the demiurge—God the Creator who, because He is an emanation from the perfect, infinite and fathomless God, is able to bring about a union with the material world. These doctrines of the mediator and the Son of God created an impassable gulf

between Christianity and Judaism. Gnosis was of course revived and further developed during the Middle Ages, especially in the Kabbalistic tradition, when the belief in God seemed too abstract and the way from God to man too long and difficult. The gnostic solution was preceded by a philosophic examination of the problem of the divine attributes, finally solved by Moses Maimonides. In order to preserve the idea of the strict singleness and unity of God, Maimonides resorted to the assumption that only negative propositions can be predicated of God and that even these negations can have only a figurative meaning. It is true that the philosophy of Maimonides and the study of philosophy in general met with strong opposition in rabbinical circles and that the Kabbala with its appeal to the human imagination became highly popular. But the doctrine of a God devoid of all plurality or corporeality remained henceforth dominant and incontestable.

This concept of God always carried with it the germ of universality. The prophets especially preached such a universalism. They proclaimed their God as the judge over all the nations in the whole earth; alien nations are instruments in God's hand for meting out punishment to Israel. The universal significance of the concepts "world" and "humanity" became much clearer during and after the Exile and Judaism was transformed from a community based upon blood into a confession. National ideals were preserved but this did not interfere with the belief in the ultimate union of all humanity, as is strikingly illustrated by the attempts to interpret certain of the Jewish religious ceremonies as symbolizing a time when all nations will be united and equal; for example, the seventy sacrifices performed on the Feast of Tabernacles were interpreted as representing the seventy nations of the globe.

Cult and rites were without significance in the religion of Moses; the Decalogue does not mention them. Fanes, altars and places of pilgrimage did not exist and the prophets radically questioned the existence of a sacrificial cult during the desert period. But in Canaan the conquerors found a widely ramified and extensive cult of fertility deities, whose favors were sought after by all kinds of gifts, magical devices, festivals and orgies. In this way pilgrimages, sacrifices and rites became popular among the Israelites and were as far as possible incorporated into the ideas of the covenant and assimilated by it. These practises gained ground rapidly. Cult

centers, particularly royal ones, acquired also political influence. The prophets fought not so much against the cultus as such as against the attempts to attach to it intrinsic value, to regard it as a fulfilment of the terms of the covenant. The polemic of the prophets, which is found also in certain psalms, was instrumental in eliminating cult centers but not in abolishing sacrifices, which remained the joy and the support of the simple man. According to the statement of Maimonides, the Torah sanctioned sacrifices and rites as a concession to the low cultural level of the people of that time.

With the destruction of the temple at Jerusalem in 586 B.C. the sacrificial cult was eliminated; the Exile allowed only for the performance of those rites which were independent of the temple; Sabbath and circumcision were regarded as signs of the covenant and their observance and practise were granted also to non-Israelites. But neither temple, priests nor sacrifices were altogether given up; only sacrifices ceased to be a matter concerning the priests alone, for the lay community demanded and obtained the right to participate in these rites and even raised the necessary expenses through a poll tax. More than this, prayer gained for itself a place of equality with sacrifice and after the Dispersion completely replaced it.

Since the days of Mosaism the idea of obligation toward one's fellow beings has been ascendant in Judaism. The system of law introduced by Moses was not the morality of the master class but of free citizens possessing equal rights. It demanded recognition of man by man. It created the ideal of "the fellow being" and of "the neighbor." This system of morality sprang from the experience of the Jew as an alien, even as a slave in Egypt, and demanded respect for human dignity. The oldest Biblical collection of laws, the *Book of the Covenant*, was undoubtedly influenced by the code of the Babylonian king Hammurabi. It greatly resembles it in systematic arrangement but towers above it in its enlightened social views. While Hammurabi, for instance, conceived law in accordance with wealth and social position, while he applied the *lex talionis* literally and allowed its brutality to fall upon the shoulders of innocent people, Israel practised the doctrine of equal rights for all and recognized the *lex talionis* only as a general principle to be sparingly applied. Post-exilic Judaism finally abolished it entirely, substituting a money fine. The prophets of Israel raised thundering accusation against injustice

and oppression of every sort. Not that social conditions among the Jews were worse than in other countries nor that Israel was ever threatened by a social revolution, but the Jewish conscience was more sensitive; social injustice weighed more heavily upon it because it was regarded as a sin against God and a denial of His covenant. The morality of the prophets has subsequently become incorporated into the morality of civilized humanity. Under its influence Israelite legislation assumed that social and charitable character which comes to light especially in *Deuteronomy*. Special attention was given to the protection and care of the propertyless and the alien (metic). God was regarded as the avenger of the poor, the father of the orphans and the friend of the metics. Since the Law wished to restrict wealth and to prevent poverty or at least to mitigate it as far as possible, the propertyless were given the right to share in the crops. Legal procedure and the administration of justice were based on principles of humanity and mildness; labor and service contracts were inspired by a highly developed social spirit. The humanization of society was developed systematically in post-Biblical Judaism. The word *tzedaka* came to designate works of charity, thus making it an obligation to aid the needy. In all Jewish communities there was established a well ordered system of poor relief, for which regular taxes were raised; and even today many Jews willingly pay the traditional tithe from their income for welfare work.

The institution of slavery was never officially abolished in Judaism. A distinction was made between a Hebrew and an alien slave. The former was permitted to sell himself for only a limited number of years. If at the expiration of his servitude he still desired to continue in his master's service he was forced to undergo the ordeal of the "boring of the ear" and to serve his master forever. Rabbinic interpretation later provided for his release in the jubilee year. The slave was taken into the family and humane treatment of him was prescribed by law. The Jewish community always made strenuous efforts to redeem a Jew who was enslaved by a non-Jew. The attitude toward pagan slaves differed little from the attitude generally prevalent in the ancient world, but mildness and considerate treatment were recommended.

The most important social laws in Judaism are those which are connected with the Sabbath ideal. Whatever the influence of the Babylonian *Sapattu* may have been upon the Sabbath insti-

tution, it was only in Israel that the idea acquired a great social importance. After six days all work must cease, even such important labor as plowing and harvesting; and not only must the master celebrate but also the slave, the metic and even the cattle must have their rest. After six years a fallow year is declared for the soil; the fields are not cultivated, the grapes are not gathered, whatever grows uncultivated belongs to the poor of the locality; debts are canceled so that poverty shall not oppress the people. After seven times seven years a jubilee year is declared for all the inhabitants of the country; in this year all the slaves become free, even those who have voluntarily entered into servitude. The soil is reappropriated and reverts to the tribe; for it is considered essentially that the land belongs to God, that men are only God's servants and metics, that they can therefore sell only the yearly produce, never the soil. The regulation concerning the jubilee and its revolutionization of property relationship was never completely carried out, but its principle proved an ever effective exhortation for a more just distribution of wealth and a means of preventing the impoverishment of the masses.

The acquisition of wealth and riches although not glorified in itself was never expressly condemned. Except as found in isolated ascetic writings the idealization of poverty as found, for example, in Francis of Assisi and the mendicant orders is absent in Jewish religious ethics. The rich were, however, enjoined to consider their wealth as a trust from God and were to use it for the relief of their fellow beings. In the matter of business relations a strict ethical code was enforced which forbade any resort to trickery and dishonesty in relations with non-Jews as well as with Jews. The Bible and the Talmud allowed the Jews in their dealings with strangers certain privileges that were forbidden them in dealings with Jews, and many Jews during the Middle Ages and modern times have doubtless practised a double code of business ethics; generally speaking, however, the mediaeval rabbis ruled that this had applied only to the old pagan peoples and explicitly emphasized the fact that it had no validity for the monotheistic peoples in whose midst the Jews of the Diaspora live. The didactic books like the *Sefer chassidim* especially emphasized the need for rigid ethical relations with non-Jews.

Interest on loans to a Jew either in kind or in money was expressly forbidden. Post-Biblical Judaism interpreted this law with extraordinary
